Abbreviations:
  Pages 31, 107, 203, 251, 301, 358, 402, 452, 502, 546, 588, 636, 680, 782, 730, 828, 920, 970, 968, 1020, 1078, 1129, 1223, 1276.
Abbey, Major Henry, Jr.: Commanding Officer at Chanute Field, Rantaul, Ill. Portrait (News note).............. 438
Accidents:
  Donald McGee, Civilian Instructor, Has Fatal Accident...................... 106
  General Hoare Injured in Forced Landing 74
  Army Balloonist Injured, Nine Taken to San Antonio...................... 113
  Congressman Aviator in Aero Accident. 149
  George Carpenter Recovering from Aero Accident 300
  Major Oscar Brindley Accident Victim. 438
  Inquiry Into Aero Accidents.......... 670
  To Investigate Aeroplane Accidents... 715
  Phil Raider in Fatal Accident......... 716
  Ace 910
  American Flier Wounded, Oscar Lange of the 104th Aero Squadron Has Been Wounded in France................ 878
Aces:
  Official List of American Aces (News note) 439
  Losses of German "Aces"............ 581
  Ace of Aces Missing (News note). Lieut. Frank Baylies Has Been Brought Down Behind the German Lines 766
  French Ace Ends Flight from Canada (News note)...................... 767
  Meissner of Brooklyn Latest American Ace 911
  Lieut. David E. Putnam is Foremost U. S. Ace 911
  Douglas Campbell, American Ace, Is Expected Home Soon (News note)..1263
  Belgian Ace Gets 24 Foe Aircraft in Lone Battle.......................1111
  French Ace Will Make Detroit Flight (News note).........................1003
  French Ace Foncks' Official Total Now 56.............................1062
Aerial Company of America: Office 26 Courtlandt St., New York City...... 400
Acrobatic Flying: By Lieut. Charles W. Keene. (Illus.).................... 726
Activities at Long Island School: The Horace Keane School of Flight at Central Park, L. I......................... 169
Addresses:
  Mr. Augustus Post Addresses Municipal Engineers 579
  Mr. G. Douglas Wardrop Addresses "The Round Table" and Other Organizations (News note)........... 150
  Lectures to Many Organizations (News note) 300
Advance Rot and Latent Defects in Aeroplane Timber, Art. by............. 674
Aerial Coast Patrol:
  Army Appoints Board to Select Location for Aerial Coast Patrol Sites on the Pacific......................... 202
  War Carried to America by U-Boats. (Art. Edit.)....................... 623
  $28,000,000 Emergency Appropriation Asked for Aerial Coast Defense..... 667
Aerial Delivery: (See Transportation).
Aerial Gunnery Schools: (See Schools).
Aerial Highway: (See Aerial Airways).
Aerial Industrial Possibilities at Madison—The Inland Waterfront City. Art. by Don E. Mowry..................... 642
Aerial League of America: Augustus Post Lecturing Extensively (News note).. 493
Aerial Mail: (See Mail Carrying).
Aerial Navigation Courses Given at Camp Dix (News note).................. 625
Aerial Photography: School Already in Operation (News note)............ 105
Aerial Route: (See Airways).
Aerial Photography Changes Things........1265
Aerial Supremacy: Need of Supremacy Pointed Out by a French General.... 389
Aero Club of America:
  Honors Garros...................... 26
  States Situation Can Be Saved by Appropriation of $3,000,000,000........ 104
  Lafayette Flying Corps Honors Aero Club 123
  Gun or Aerial Torpedo? (Art.)....... 148
  Inner Problems of Aircraft Situation Made Public and Steps Proposed for Solution. (Edit.)................ 199
  Letter from Mr. Hawley to President Wilson 199
  Aero Club Supporting Secretary Daniels and Admiral Benson in Fight for Extension of Navy Personnel........ 713
  French "Ace" Ends Flight from Canada (News note)...................... 767
  Ace of Aces Missing (News note)..... 766
  Official List of American Aces (News note) 439
  Mr. Henry Woodhouse's Work Commended 817
  Meissner of Brooklyn Latest American Ace 910
  Lieut. David E. Putnam Is Foremost U. S. Ace......................... 911
  Clifford Prodger Offers to Fly to Europe 925

PAGE

  Aero Club Medals Are Awarded to 33 Aviators (News note).............. 953
  The War Medal and Diploma of the Aero Club of America..............1110
  Belgian Ace Gets 24 Foe Aircraft in Lone Battle.......................1111
  Douglas Campbell, American Ace, Is Expected Home Soon...............1263
  Royal Geographical Society Honors Captain Bartlett....................1281
Aero Club of Pennsylvania: Opens New Library (News note).............. 105
Aerodynamics: 914-918-1116
Aero Engineering Squadrons: U. S. School of Military Aeronautics, Mass. Institute of Technology, Boston, Mass.... 405
Aerological Stations: New Aerological Stations Planned..................... 669
Aero Mail Beats Thunderstorms and Breaks Records (News note).............. 716
  5,000 Miles Covered by Air Mail (Aircraft Review)..................... 719
  Captain A. C. Weidenbach, the Head of the Aeromail Fliers (Portrait)...... 715
  Landing Place for Philadelphia Selected (News Note)...................... 202
  Aero Mail Appropriation in Post Office Bill (News note)................. 533
  London-Paris Aero Mail Being Studied by Postal Administration........... 672
  Aero Mail Extended to Include New York-Boston Service............... 667
  Supervisor of Aero Mail, Captain Adolph C. Weidenbach of the Signal Corps (News note)...................... 715
  Aero Mail Envelopes Bring $10,000 for Athletic Equipment................ 864
  Aeroplane Mail Hours............... 864
  Cleveland and Chicago to Ask for Aerial Mail Line........................1057
  Aero Mail Expansion Planned.........1070
  To Be Extended to Cleveland and Chicago 1071
  New Aero Mail Record..............1071
  Aero Mail Triumphs Over Storms.....1071
  Permanent Aerial Mail Service Great Success 1119
  Aero Mail Head Thanks Hylan........1191
  Weekly Aero Mail in Canada.........1193
  Aerial Mail for Chicago and Cleveland.1261
  Huns Quit Aero Mail...............1269
Aero Making in Detroit: The Beginning of Important Industry. By A. A. Templeton 57
Aero Map of Kelly Field Being Prepared (News note)...................... 669
Aeronautics:
  Philadelphia in the Aeronautic Industry (Industrial Dept.). By W. R. D. Hall 57
  Aeronautic School at Carnegie (News note) 28
  $188,000,000 for Navy Aeronautics (News note)...................... 26
  Survey Committee Named on Aeronautical Work..................... 105
  Military Aeronautics in South and Central America...................... 202
  New Department of Aeronautics Is Probable Now...................... 249
  New Aeronautic Companies Organizing in Increasing Numbers............. 346
  French Congress of Civil Engineering Considers Aeronautic Problems (News note) 348
  Army Aeronautics Separated from Signal Corps by President Wilson's Order (Edit.) 531
  Manley Twenty Years in Aeronautics (Aircraft Trade Review)........... 628
  Bevoine Appointed Italian Commissioner for Aeronautics in America (News note) 625
  Model Aeroplane Building as a Step to Aeronautical Engineering........... 685
  Aeronautics Dominate S.A.E. Summer Meeting 770
  Commercial Aeronautics in Siam (Aircraft Trade Review).............. 865
  Aeronautic Libraries: Air Service Has Close to 2,000 Members to Establish Forty Aeronautic Libraries.......... 817
  Aeronautics in 1783 (News note).....1216
Aeronitis:
  Pages 60, 122, 166, 220, 267, 314, 364, 410, 458, 508, 595, 644, 666, 726, 788, 836, 882, 928, 972, 1024, 1032, 1132, 1184, 1232, 1284.
Aeroplanes:
  Characteristics of the Leading Aeroplanes, Hydroplanes and Flying Boats, 1917-1918 (Illus.).................. 36
  Every Military Aviator Aught to Know What His Own and the Enemy's Machine Can Do and How They Look. By Henry Woodhouse (Illus., p. 112) 42
  Aeroplane Parts at a Glance (Illus.)... 52
  British Naval Vessel Taking Gasoline to a Seaplane Compelled to Descend for Want of Fuel.............Cover No. 3
  Drop News to Belgians Aid Liberty Loan (News note).................. 229
  Aid Liberty Loan (News note)......... 250
  Allies More in Need of Planes Than Soldiers 297
  A Spad Being Assembled at One of the French Camps (Illus.)............. 360

PAGE

  A German Aeroplane Captured by the British in Palestine................. 362
  The Uses of Jigs, Fixtures, Gauges and Tools in Aeroplane Manufacture. By R. Borlase Matthews............... 396
  Getting a French Avion-de-Chasse Ready for its Experimental Flights (Illus.). 398
  The Aeroplane of the Aviation Reserve Corps, New York City Police Dept., in the Recent Police Parade........ 536
  The Advantage of Sending Mail by Aeroplane 578
  Detachable Fuel Tank for Aeroplanes (News note)...................... 579
  The Aeroplane Which Lieut. Winslow and Campbell Used in Bringing Down the First German Aeroplane (News note) 580
  103 Aeroplanes Fly for the Red Cross (News note)...................... 579
  Calculation of Stresses in Aeroplanes. By S. E. Slocum.................. 633
  Aeroplanes in Enemy Radio Hunt (News note)...................... 669
Aeroplanes for Independence Day Unity.... 689
 Parade (News note) 609
  Repairing a Damaged Plane at One of the American Flying Fields in France (Illus.) 717
  When One of the Defenders of Paris Made a Bad Landing (Illus.)....... 670
  To Investigate Aeroplane Accidents.... 715
  Cotton for Aeroplane Wings (Aircraft Trade Review).................... 718
  Spurs Aeroplane Output (Aircraft Trade Review) 718
  At 2,000 Feet Somewhere in the U. S. (Illus.) ....Cover No. 15
  British Parliament Urges Need of Thousands of Aeroplanes to Win the War in Air........................... 714
  A Recent German Victim; Brought Down by One of Our Squadron (Illus.) 731
  Moving Pictures from Aeroplane (News note) 767
  Aeroplane Carries Cargo............. 790
  Crating an Aeroplane for Railroad Transport (IIllus.) 790
  Representative Allied Aeroplanes of 1917, from "The Aeroplane" (Illus.). 778
  Diagram of German Aeroplanes that Have Been Used During 1917 (Illus.) 778
  A British Fighting Plane Setting Out to Engage the Enemy (Illus.).Cover No. 16
  Offer 10,000 Planes to Fly to France (Edit.) 815
  Chicago Aeroplane Inquiry Probably Ordered by Hughes................. 818
  Big Plane Coming for First Trip (News note) 818
  Cadet Aviators Constructing Aeroplanes at Rockwell Field, San Diego (Illus. (News note) 818
  Major Bishop Brings Down His 72nd Hun Plane (News note)............. 818
  Mimic Night Air Battle Fought Over Baltimore (News note).............. 818
  Flying Bombing Planes Across the Atlantic (N. Y. Times)............ 888
  Thousands of Bombing Planes (Edit. N. Y. Times)...................... 888
  Aeroplanes to Bring Victory to Allies. By Gen. J. M. G. Malleterre........ 887
  Du Pont Gives Y.M.C.A. Aeroplane.... 864
  Aeroplane Plant for Y. M. C. A. (News note) 909
  A German Machine Captured by the French and Subsequently Used for Training Purposes (Illus.).......... 821
  Official Photograph of a Squadron Formation Taken from One of the Military Aeroplanes (Illus.)....Cover No. 18
  America's First Achievement in Providing Bombing Aeroplanes (Edit.)...... 861
  British Aeroplane Being Loaded with Bombs Previous to a Raid Into the Enemy's Country 873
  New Material for Aeroplanes (Aircraft Trade Review)..................... 912
  Ash Trees for Aeroplanes (Aircraft Trade Review)..................... 912
  To Ascertain the Speed and Direction of Aeroplanes Over the Water (Illus.) 914
  Transfer Made Aeroplanes (News note).1163
  Steel for Aeroplane Wings (Aircraft Trade Review).....................1166
  A Squadron of American Aviators Practicing Formation Flying....Cover No. 23
  An Allied Battleplane Engaged in Patrol Work, Flying Over a Bank of Clouds. Cover No. 22
  One Aeroplane Photographed from Another ....Cover No. 21
  Christening the Aeroplane Presented by the Inhabitants of the City of Huddersfield to the Canadian Government ....Cover No. 20
  An Evening Flight at one of the American Training Schools.......Cover No. 19
  Italian Airmen Protecting the City of Venice from Air Attack....Cover No. 17
  At 2.000 Feet Somewhere in the U. S. (Illus.) ....Cover No. 15
  A Remarkable Demonstration of Formation Flying at One of the American Training Fields (Illus.)....Cover No. 14

PAGE

- Three French Training Machines Maneuvering in Close Formation at an Aerial Review in France (Illus)...... Cover No. 11
- Soldiers and Sailors Cheering the Maneuvres of a Naval Aviator at Key West, Florida........Cover No. 6
- An American Seaplane on U-Boat Patrol (Illus.) 1279

Aeroplanes (Types):
- Albatross Type:
  - *German Scout forced to Land by a Pilot in the British Royal Air Force..1080
  - The Cockpit and Sand Motor Placement of a German Albatross (Illus)....... 305
  - Albatross Type "CV" Fighter (Illus).. 540
  - The Chassis of the Albatross C-V Type. 540
- Austrian Berg: Single-Seater Fighter (Illus.) 720
- Avro: One of the Twin-Motored Bombing Avro Planes Manufactured by the A. V. Roe Co.......... 205
- Breese Penguin: Designed by S. S. Breese, equipped with a Two-Cylinder 26 H.P. Charles Lawrence Motor.......... 153
- Brequet:
  - A Brequet in Flight; One of the Most Efficient Fighting Machines of the French Air Service (Illus.).......... 29
  - A Two-Passenger Brequet Machine Equipped with Twin Lewis Guns About to Land (Illus.).......... 40
  - Fuselage of a French Brequet Bombing Machine with a Renault Installed (Illus.) 779
- Bristol Bullet:
  - Bristol-Curtiss Aeroplane Has Successful Test (News note).......... 106
  - The Bristo Fighting Two-Seater, with a Gun Ring at the Back (Illus.)...... 455
- Caproni:
  - Preparing Caproni Triplane for the Mounting of Their Fiat, or Isotta-Franschini Motors (Illus.).......... 397
  - A Twin-Motored Italian Caproni (Illus.) 681
  - The Remarkable "Baby" Caproni Triplane Scout, the Smallest Member of the Caproni Family (Illus.)..........1165
  - A Squadron of the Famous Caproni Triplanes Which Have Been Doing Such Wonderful Work (Illus.)..........1228
  - A Caproni Hydroaeroplane Equipped with Three Fiat Motors, 300 H.P. Each (Illus.)..........1276
  - A Caproni (American) Biplane in Flight (Illus.) ....Cover No. 26
  - "First Liberty Caproni," Which Is Being Built for Army Use (Illus.)......... 120
- Caudron:
  - Illus. Type G Used Extensively for Elementary Training in the French Air Service (Illus.).......... 494
  - Scene of One of the French Flying Fields, with Some of the Elementary Caudron Training Machines (Illus.).. 495
  - A Training Caudron Biplane (Illus.)... 638
  - A French Caudron Biplane (Illus.)..... 639
  - Caudron Training Machine (Illus.)..... 731
  - The Caudron R. 11 Type of French Bombing Biplane, Twin-Motored (Illustrated) 1116
- Continental: The Continental K.B. 3T Training Tractor. By John F. McMahon (Illus. desc. line drawings)... 316
- Curtiss JN Training Tractor at the Horace Keane School of Flight, Central Park, L. I. (Illus.).......... 201
  - The Hispano-Suiza Motored Curtiss Biplane Used for Aerial Mail Carrying 863
- De Haviland:
  - One Day's Output of the Dayton-Wright Airplane Company..........1125
  - An American-Made De Haviland 4 Being Assembled (Illus.)..........1277
- Fokker: A German Fokker Monoplane Exhibited at the "Liberty Land" at the 69th Armory, New York City (Illus.) 392
- Friedrichshaven:
  - 450 H.P. Gotha 11 Fighting and Bombing Biplane Line Drawings (Illus. desc.) 698
  - Bombing Biplane (Illus.).......... 630
  - Bombing Biplane (Illus).......... 677
- Gotha:
  - Bombing Aeroplane Brought Down in Belgium While Returning from a Raid in England (News note).......... 28
  - The Engine Housing of the German Gotha Brought Down Recently in Belgium (Illus.).......... 30
  - Three Views of the Gotha Bombing Biplane (Illus.).......... 590
  - A German Gotha Captured by the French Air Service in the Environs of Paris (Illus.) 783
  - The First Photograph of a Complete Gotha "Grossflugzug" Which it Is Believed Has Been Published of This (Illus.) 831
  - Three-Passenger Two-Motored Gotha Bomber (Illus.) 960
- Halberstadt Werke: A German "Mystery" Biplane (Illus., desc.).......... 866
- Handley-Page:
  - The Two-Motored Handley-Page Bombing Machine (Illus.).......... 304
  - Three Views of a Model of the Handley-Page Machine (Illus.).......... 881

PAGE

- Liberty: Big Liberty Plane Production in Detroit 768
- Langley: The Langley-American Made Handley-Page Bombing Machine, Which Was Christened July 6th...... 909
- Lawson: The Lawson M.T. 2 Tractor Biplane—Hall-Scott Motor.......... 584
- Nieuport:
  - Illus. Four Nieuports and a Spad Being Groomed for Work in Flanders.......... 505
  - A Group of Nieuports at an Aviation Field in France Getting Ready for the Day's Work (Illus.).......... 669
  - Scale model of a Nieuport Made of Wood (Illus.).......... 685
  - French Nieuport Machines Lined Up for Inspection at the American Aviation School in France (Illus.).......... 682
- Penguin: A "Penguin" or "Grasscutter," with Reduced Wing Spread, Which Cannot Rise More Than Six Feet Off the Ground (Illus.).......... 716
- Pfalz:
  - Pfalz Single-Seater Fighting Plane (Illus.) 537
  - The Pfalz Single-Seater Fighter (Illus.) 867
- Roe: A Group of Twin-Motored A. B. Roe Fighting Planes (Illus.).......... 111
- Rumpler:
  - Captured on the Oise Front (Illus.).... 109
  - The C, 1V Rumpler Biplane Above, Using a 260 H.P. Mercedes Engine, and Below with a 250 H.P. Matbach (Illus.) 156
  - A Rumpler Type of German Machine Captured by the French (Illus.)...... 637
  - A German Rumpler Type Biplane (Illus.) 777
  - A German Rumpler Type Machine Captured by the French (Illus.).......... 777
  - Two-Passenger 1917 Rumpler, Used for Fighting, Bombing and Photography (Illus.) 960
  - A Rumpler Type of German Machine Captured by the French (Illus.)..... 963
- Salmson: Views of the Salmson Biplanes (Illus.) 1217
- S.E.5 Biplane R.A.F. Design (Illus.).... 403
- Sopwith: A Sopwith Biplane at the French-British Front (Illus.).......... 29
  - A Sopwith Triplane, Photograph of Which Appeared in a German Periodical (Illus.).......... 492
  - The Sopwith Triplane (Illus. desc. Line Drawings) 543
- Spad:
  - A French Spad Biplane with 150 H.P. "Pusse" (Compressed) Hispano-Suiza Engine (Illus.).......... 776
  - A French Spad Biplane, Single-Seater, Used for Pursuit Work (Illus.)......1114
- S.P.A.D.: French Machine of the Esquadrille Returning to Its Aerodrome from a Trip Over the Lines (Illus.)..1277
- Sikorsky: Two Views of a Four-Engine Biplane (Illus.).......... 589
- Standard: Standard Aeroplane Gets to Capital in Record Time (News note). 249
- Voisin: The First Photograph of the Voisin Triplane Published in America (Illus.) 715

Aeroplane Clocks: One of the Most Efficient Shock Absorbing Devices designed to Mount Aeroplane Clocks (Illus.)..... 865

Aeroplane Mail Service: In Russia (News note) 299

Aero Mail Hours: (News Note).......... 864

Aeroplane Mechanics: No Shortage of Aeroplane Mechanics (News note).......1015

Aeroplane Mechanics' School in Detroit: (Aircraft Trade Rewiev).......... 440

CONGRATULATORY MESSAGES

Distinct Contribution to Aeronautical Journalism

Mr. Howard E. Coffin, Chairman of the Aircraft Board, writes:

"In reply to your letter of February 18th, asking for my opinion of the place filled by AERIAL AGE during the past year, I feel that, as an interesting record of events in the aeronautical world, attractively presented and so edited as to appeal to the magazine reader who has an interest in flying as well as to the more technical man, AERIAL AGE is a distinct contribution to aeronautical journalism.

"I desire to extend my personal appreciation of the strong support given by your paper to the aviation program."

Splendid and Most Effective Work

Mr. Alan R. Hawley, President of the Aero Club of America, writes:

"I wish to extend to you my most cordial congratulations upon the anniversary of the splendid and most effective work of the publication AERIAL AGE, which completes another year of usefulness for the aeronautic industry. You have covered the ground most completely in all technical matters and have kept thoroughly up to date in all matters of exceptional interest to this fast growing and broadly developing science and art.

"It has given me great pleasure to read the record each week and I have gained great information from its interesting pages.

"Please accept my best wishes for the coming year, which is fraught with such grave responsibilities which are daily being placed upon the shoulders of those responsible for the development of our aerial defenses. Now, more than ever it is necessary for the entire industry to stand together and to carry the military activities of our aerial forces over the lines and to strike at the very heart of the common enemy of the Allies, and there is no doubt that the aeroplane is the most effective weapon to bring complete and irreparable disaster to our enemy and the 'enemy of mankind.'"

Review of the Aeronautic World

Rear Admiral Robert E. Peary telegraphed us as follows:

"Congratulations to AERIAL AGE in commencing its fourth year of constructive patriotic work. To the busy man in Washington, AERIAL AGE comes as a weekly review of the aeronautic world through which he can get the detailed information of events in aeronautical developments and the status of the aeronautic industry. I wish AERIAL AGE additional strength in its fourth year of National usefulness."

Scrupulously Maintained the High Standard

Major B. D. Gray, of the Production Engineering Department of the Signal Corps, writes:

"I have your very good letter of February 18th. In reply I am obliged to confess that my time is so fully occupied with the business of my department that I do not get time to do more than glance hastily through your paper.

"I realize that I am missing a lot of instructive information but I am sure that you are scrupulously maintaining the high standard at which you have always aimed."

Incomparable Foresight

Mr. Henry A. Wise Wood, Vice-President of the Aero Club of America, writes:

"I wish to congratulate AERIAL AGE upon the superb work it has done for our country, and its incomparable foresight.

"It has been fearless in the expression of its patriotism, and unshakeable in pressing upon the authorities its determination that America shall be equipped to master Germany in the air."

Very Valuable

Mr. David L. Gallup, Research and Experimental Engineer of the Nordyke and Marmon Company, writes:

"I am glad of the opportunity of expressing my appreciation of the manner in which information relative to aeroplane work is given out in the AERIAL AGE WEEKLY. The material is not only of great interest to the reader, but is also very valuable. Let me wish you every success in your future work in connection with this paper."

The Mainspring of Literary Aviation

Mr. W. T. Thomas, Vice-President of the Thomas-Morse Aircraft Corporation, pioneer designer, writes:

"The educational work which has been done by AERIAL AGE during the last three years has been of inestimable value to our Aircraft Industry, and it is only through the untiring efforts of some of the early "believers" in Aviation that it has received the consideration from the public, and the Government, which it has.

"There is still a great deal to do along these lines, and we know that AERIAL AGE will be 'on the job.' The future of Aviation is as bright as ever, and I believe the skin has so far just been scratched."

Appreciation

Glenn H. Curtiss, the pioneer inventor, writes:

"I am very glad to take this opportunity to express my appreciation of the work which AERIAL AGE has done in the promotion of aeronautics and in the chronicling of national and international aeronautic activities. I look forward with much pleasure to each issue."

452715

OUR THIRD ANNIVERSARY

TODAY AERIAL AGE celebrates its third birthday. True it is that we are growing compared with the industry we represent, but we believe that our three years of existence has done much to broaden and elevate the business, and to increase interest in and respect for the aeroplane and the internal combustion engine as an adjunct of modern warfare, and, after the war, as a medium of speeding up commerce and the inter-communication of nations.

AERIAL AGE was established to help pull American Aeronautics through those "Dark Ages" when Congress was allowing only about $100,000 a year for aeronautics. Half of that sum had to be spent in maintenance and it took a whole lot of energetic workers to create public interest to force Congress to give more and to enthuse a few sportsmen to purchase aeroplanes for sport.

It required courage to adopt the name AERIAL AGE. At that time the possible value of aeroplanes for military purposes was still a matter of opinion—and the general opinion was that aeroplanes could not be more than scouts. It was held that aeroplanes could not be used for effective offensive and defensive because the recoil of a gun or the dropping of a bomb large enough to do damage would upset them.

The possibility of large areoplanes equipped with two motors was denied on these grounds: 1, That the thickness of the wings of the aeroplanes must increase in proportion to the span of the wings; 2, That a machine equipped with two motors would spin around out of control as soon as one of the motors stopped.

The very term "factor of safety" was unknown at the time and every machine built was an experiment.

AERIAL AGE was established in March, 1915. Clouds from the war storm which was raging in Europe were beginning to darken America's horizon and energetic work was necessary to awaken this country to the need of aerial preparedness on a large scale.

The United States Army and Navy combined had less than fifty aviators, including those in charge of the administration of the Aviation Section. There were no dirigibles or kite balloons in either the Army or Navy.

The aeronautic industry consisted of a handful of courageous pioneers who had and were doing business at a loss. Congress had only allowed $300,000 for Army aeronautics and $1,000,000 for Navy aeronautics. The Allied countries were ready to give substantial orders, but they would only place orders for prompt deliveries, and as the manufacturers were not in a position to deliver, they would not place the orders.

The editors of AERIAL AGE realized that the war would be decided in the air; and that it was essential for the security of the United States to develop a substantial aeronautic industry, so as to have large sources of supplies of aircraft to meet an emergency. They undertook the huge tack of getting together the factors necessary to create a large industry. That meant the creating of public and official interest in aeronautics in America; making known to the Allies what American manufacturers could do and to make known to American manufacturers and prospective manufacturers the needs of the Allies. It meant more than publishing a good national technical and trade journel well—it meant also the shaping of courses of events in the industry, the directing of purchases and arranging the financing of manufacturers, and fathering the young industry in a general way supplying speakers and moving pictures; supplying "pen pictures" of the status of different aspects of aeronautics to government officials, etc.

To do this AERIAL AGE had to establish four separate departments, one to do the national defense work, one to do the "Service and Advisory" work, one to do the regular work of publishing a national technical and trade journal and one to run a "photo and news service" to supply the aeronautic movement and the press and public with special aeronautic information and educational material.

These four departments have been maintained throughout these years and have rendered invaluable services to Country, to the Aeronautic Industry and to the Aeronautic Movement in general.

With a glance backward, over a year of constructive service, AERIAL AGE looks forward to even greater opportunities for its Fourth Year.

GREAT NATIONAL SUCCESS OF OFFICIAL FRENCH AERIAL WARFARE EXHIBIT ASSURED

Opening of Exhibit in New York International Function

IT has been some time since an art exhibition has opened in New York with so much eclat as attended the first showing of the pictures by Lieut. Henri Farre, representing the "Sky Fighters of France." Gov. and Mrs. Charles S. Whitman were the guests of honor, and the Governor made a speech in praise of the pictures.

Alan R. Hawley, Henry Woodhouse and other members of the Aero Club of America attended, and many American and French aviators and army officers gave a military color to the rooms which were thronged with persons prominent in society, upon whom the pictures of battles in the air made a profound impression.

The pictures are shown in the Anderson Galleries, formerly the home of the Arion Club, a well known German society, and beginning today will be on public view, the proceeds benefiting the children of French aviators killed in the war.

The artist, Lieut. Farre, is himself an aviator, who has been promoted to the rank of observer and bombardier of the first group of the Bombardment Escadrille and has received the Croix de Guerro. He took part in practically all the raids over German cities and munition centres, such as Karlsruhe, Dieuze, and Metz, and has flown over all parts of the battle lines. It is the sights Lieut. Farre has seen from his aeroplane and the air battles in which he participated that he has put on canvas.

Shows Courage In Art

It is startling enough, at first thought, to dream of depicting such events in pictures, but Lieut. Farre is an able, well trained artist—he is a graduate of the Beaux Arts and a frequent exhibitor at the Paris Salon—and the same courage he used in fighting air battles stood him in good stead when painting them.

They are extremely realistic and it was apparent that, in spite of all the photographs and written descriptions that have been published, many of the visitors were realizing for the first time the wonders and horrors and even beauties of the new manner of fighting. The works are astonishing as pictures, but have been painted with such conviction that one ends in accepting them literally. Had one any doubt as to the truth of the pictures the doubt would have been dispelled by the sight of the quick acceptance of the pictures by the many aviators who were present at the reception. The interest in the paintings by Lieut. Farre's fellow flyers was a rather pathetic thing to watch.

Made His Studies In Flight

The artist, of course, did not paint the pictures from an aeroplane. One cannot paint realistically while flying at the rate of 100 miles an hour, but Lieut. Farre devised a method of jotting down color memoranda while in flight and finished the pictures in the calm of a studio.

He touches many phases of air fighting. One sees the machines circling as innocently as birds over mountain masses of cloud, with bits of blurred darker tones where the earth ought to be. One definitely realizes the true direction of the earth in the next pictures of the series, for one of the machines—fortunately a Taube—has been winged and sinks with a trail of smoke straight downward.

The artist strikes a still more dramatic note in the painting that shows the return of the body of Capt. Fequant, pilot, by Sergeant Niox after a reprisal bombardment of Saarbruck. In the fight Capt. Fequant, who was standing up in the machine, was hit by a German bullet and fell partly over the side of the machine. The pilot, with a badly wounded hand, held the dead body where it lay and guided the plane back to the field from which he had started.

The realism of these pictures is of a new sort, and is very different from the realism of Verestchagin, who deeply interested a former generation with his war pictures, but it ought to interest as greatly the general public as it did yesterday the Governor and his staff.

Gov. Whitman in his speech expressed the appreciation of the people of the State for the services rendered by Lieut. Farre, not only as an artist but as a soldier and an aviator. "Some of the men whose faces look down upon us from these walls," said the Governor, "live only in the memory of those who love and honor and cherish the memory of great men and great deeds. Some of these villages portrayed in the pictures exist only on canvas now. They have been obliterated, wiped off the face of the earth, but the men and women from these villages have helped to make the history of which the Anglo-Saxon race, of which the civilized world, is going to be tremendously proud in the years that are to come.

"I am sure that all Americans desire to help the orphan children of the dead aviators who have given their lives for the cause which is just as much our cause as it was their cause."

Among those present were the Duchess de Chaulnes, Marquis and Marquise de Polignac, Mrs. Benjamin Thaw, Mrs. Charles Steele, Mrs. Harry Hamlin, Mr. and Mrs. William H. Crocker, Mr. and Mrs. Edmund L. Baylies, Miss Van Rensselaer, Mr. and Mrs. Jordan L. Mott, Mr. and Mrs. Charles A. Van Rensselaer, Stephen Van Rensselaer, Lieut. Walter Seligman, Mrs. Frederick Lewisohn, Miss Janet Richards, Dr. Frank Northrop, Stephanne Lausanne, Morton Paton, J. F. D. Lanier, Gaston Liebert, the French Consul-General to New York; Mr. and Mrs. Walter E. Maynard, Mr. and Mrs. R. A. C. Smith, Mrs. E. Henry Harriman, Mrs. Charles Dana Gibson, Francis W. Crowninshield, Mrs. Newbold Le Roy Edgar, Mrs. Charles H. Marshall, Karrick Riggs, Miss Pauline Riggs, Miss Frances Ogden, Mrs. John J. McCook, Mr. and Mrs. Walter Rosen, Mr. and Mrs. Goodhue Livingston, Mrs. George Rose, Mrs. W. Astor Chanler, Mr. and Mrs. Leo Everett, Howard Taylor, Mr. and Mrs. Gouverneur M. Carnochan, ex-Ambassador Henry White, George Peabody Wetmore, Mrs. Henry P. Davison, Wadsworth R. Lewis, William W. Miller, Mr. and Mrs. William H. Woodward, Mrs. Stuart Duncan, Mrs. Howard G. Cushing, Mr. and Mrs. F. Gray Griswold, Miss Mary Cass Canfield, Mrs. William D. Sloane, Prince Pierre Troubetskoy and Allison Armour.

There were also present Admiral Fiske, Capt. Noble E. Irwin, Commandant G. Tulasne, Andre Tardieu, French High Commissioner; Lieut.-Col. Charles E. Lee, Lieut.-Col. Ira F. Fuvell, Lieut. Pollock, Sergeant Balsley, Lieut. Flashaire, Brig.-Gen. Kenyon, Pierre Mali, Douglas Wardrop, Alexander McClure, Geoffrey Butler, Jacques Copeau and various members of the company of the Theatre du Columbier, as were also Mr. and Mrs. Lucien Muratore and Mrs. Edward H. Sothern.

The Executive Committee comprised the following personalities:

Mrs. William A. Chanler, Chairman; Commandant G. Tulasne, Mrs. Edmund L. Baylies, Mrs. John Magee, Mrs. Walter E. Maynard, Mr. Frank Crowninshield, Lieutenant Henri Farre, Mr. Alan R. Hawley, Baron Charles Huard, Mr. Henry Woodhouse, Mr. Walter E. Maynard, Treasurer; Mr. Bennett E. Tousley, Secretary.

The National Committee comprises:

Dr. Edwin Alderman, Pres. of University of Virginia; Hon. Robert Bacon, Mrs. William Allen Bartlett, Chairman Aviation Committee, National Special Aid Society; Mr. George Gordon Battle, Hon. James M. Beck, Mr. Edwin Blashfield, Mrs. William H. Bliss, Mr. Louis Boissevain, Mr. Adolphe Borie, Mr. W. H. Brevoort, Mr. I. Tucker Burr, Mr. Walter Camp, Miss Alice Carpenter, Chairman, New York Branch, Woman's Naval Service; Mr. J. Parke Channing, Chairman of the Engineers' Council; Mr. Frederic R. Coudert, Mr. William H. Crocker, Miss Marjorie Curtis, Mrs. Henry P. Davison, Mr. Henry J. Davison, Mr. William Adams Delano, Mr. Edgar B. Davis, Chairman National Defense Committee of the Rubber Association of America; Mr. Morton B. Downs, Duchesse de Chaulnes, Mr. Finley Peter Dunne, Mrs. Newbold LeRoy Edgar, Mr. Charles E. Eliot, Mr. J. B. W. Gardiner, Mrs. Charles Dana Gibson, Mrs. Jay Gould, Mrs. F. Gray Griswold, Mr. John Hays Hammond, Jr., Mrs. E. H. Harriman, Mr. Thomas Hastings, Mr. McDougall Hawkes, Mrs. Ernest Iselin, Mrs. Lewis Iselin, Mrs. Cadwalader Jones, Mrs. Otto H. Kahn, Dr. George F. Kuntz, Mr. Thomas W. Lamont, Mrs. Lewis Cass Ledyard, Hon. G. Liebert, French Consul; Mr. I. Chauncey McKeever, Mr. Eugene Meyer, Jr., Council of National Defense; Hon. Geo. Von L. Meyer, Mr. Edwin G. Merrill, Mr. William Fellowes Morgan, Mr. Chas. A. Munn, Mr. Frank A. Munsey, Mr. Alfonso de Navarre, Prof. Henry Fairfield Osborn, Rear Admiral Robert E. Peary, President, Aerial League of America; Marquis de Polignac, Mr. Augustus Post, Mrs. Ralph Pulitzer, Mr. William Reick, Mrs. Charles Van Rensselaer, Chairman National Aeronautic Committee, Woman's Naval Service; Mrs. Schuyler Van Rensselaer, Mrs. Douglas Robinson, Mr. Charles H. Sabin, Mr. Charles Scribner, Mrs. W. D. Sloane, Mrs. Wilard Straight, Mrs. Herbert Bayard Swope, Mr. Benjamin Thaw, Mrs. William Payne Thompson, Mr. A. Kinnaird Tod, Mr. Bennett E. Tousley, Mr. Charles Hanson Towne, Mrs. Cornelius Vanderbilt, Mrs. Fiske Warren, Mr. Lloyd Warren, Mr. Charles D. Wetmore, Mr. Henry J. Whigham, Hon. Henry White, Hon. Charles S. Whitman, Governor of the State of New York; Mrs. Charles S. Whitman, Mr. Louis Wiley, Mrs. M. Orme Wilson, Mr. Bronson Winthrop, Mrs. Henry A. Wise Wood, Vice-Chairman, National Aeronautic Committee, Woman's Naval Service.

Owing to the general request received the Executive Committee have decided to lengthen the daily exhibit to 10 o'clock in th evening, instead of 5 o'clock as had been decided previously.

First Showing of First Aerial Warfare Films

On Monday, March 11th, the first showing of the remarkable Official French Aerial Warfare films was made. These consist of a series of six films dealing with the making of aeroplanes and motors, the training of aviators, and the different phases of aerial warfare, such as fighting, directing artillery fire, reconnoitering, and aerial coast patrol.

These films were shown daily and attracted large crowds of aeronautic and military authorities and engineers who stated that they were of great value from a military and professional standpoint.

Addresses were delivered by such experts as Lt. Geo. Flashire, the French Ace; Lt. Hunt, Royal Flying Corps; Capt. Berroetta, the French Flying Corps, and Col. Bloomfield, of the Royal Flying Corps.

From New York the exhibit will go to Philadelphia, and then to Washington.

A large number of requests have been received from different cities who are anxious to secure the exhibit and schedule is now being made by the Executive Committee to extend plans to include all the American cities desirous of securing the exhibition in their midst. The officers of the Executive Committee are at 297 Madison Avenue.

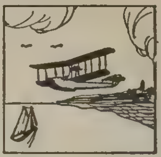
AN INDUSTRIAL DEPARTMENT

WITH its present issue AERIAL AGE inaugurates a new service for its reading clientele, and for the constructive development of the aeronautical industry. During the last year there has been a demand for authoritative information on the part of aircraft manufacturing companies concerning the special opportunities and facilities which industrial centers had to offer them in the matter of factory sites and transportation service. AERIAL AGE'S Service Department is co-operating with the Chamber of Commerce of the important cities in presenting authoritative facts to the aircraft concerns and towards this end commences this week on page 57 a series of articles which will be of immense value to the aircraft manufacturing interests.

The first of the series presents the case for Detroit, by Mr. Allan A. Templeton, the President of the Detroit Board of Commerce; for Philadelphia, by Mr. W. R. D. Hall, Secretary of the Philadelphia Chamber of Commerce, and for Birmingham, Alabama, by Blanks Everett, Secretary of the Birmingham Chamber of Commerce.

The series will be continued hereafter in the first issue of each month.

THE NEWS OF THE WEEK



Aero Club of America Honors Garros

Lieutenant Roland G. Garros, the famous French aviator, who was captured by the Germans but who escaped from a prison camp early in February, was informed by the Aero Club of America that he had been awarded a "unique" medal for the service he rendered aviation by inventing a type of aeroplane on which a machine gun is fired through the propeller.

Reporting an interview, the New York *Times* quotes Garros as follows:

"What are my plans? Of course, I am going back to the front in the chasse escadrille as soon as I have had some training and can get abreast of the new developments. That will take about a month, I expect. You know it is like coming back from the grave. One has to learn over again.

"When I was captured, air fighting was regarded as extraordinary, (Garros omitted to say that he was the pioneer in that branch, and that the first three aerial combats were fought by him.) and my aeroplane had only a ninety horse power rotary motor, with a speed of seventy miles an hour and a 'ceiling' of about 3,000 meters. Now, they tell me, the fighting aeroplanes attack in regular fleets at a speed of over 100 miles an hour.

"I hear that America's air contribution is going to be something remarkable, and many persons seem to be tending to the opinion that the war will finally be won in the air. Personally, I cannot say yet, but I am looking forward eagerly to another go at the Boches. Remember, I have a big score against them to pay for the last three years."

Secretary of War Thanks Mrs. Bartlett

As chairman of the Aviation Committee of the National Special Aid Society, Mrs. William Allen Bartlett has received the following letter from Acting Secretary of War Benedict Crowell, approving of the work of raising money which is being done by the committee through its Treasure and Trinket Fund:

WAR DEPARTMENT,
Office of the Assistant Secretary.
Washington, D. C., March 4, 1918.

Mrs. William Allen Bartlett, Chairman, Aviation Committee, National Special Aid Society, 259 Fifth Avenue, New York, N. Y.

Dear Madam: The War Department is gratified that the Aviation Committee of the National Special Aid Society, through its "Treasure and Trinket Fund," has raised and spent since September, 1917, $30,000, meeting the needs of our aviators.

This useful and patriotic service should be generously helped by our people, and I want to congratulate your committee on the fact that it has been able to supplement what the Government is doing for these men, and to make them feel that the personal good-will and affections of our people follow them in their difficult and dangerous work. Very sincerely yours,

BENEDICT CROWELL,
Acting Secretary of War.

The committee has raised for its aviation work even more than the sum the Acting Secretary mentions in his letter, having made through its fund almost $40,000 since September. It is to begin a big drive which it hopes will draw every old piece of silver and gold from every treasure trove in the country at an early date.

Large Planting to Increase Output of Castor Oil Lubricant

The War Department, through Major-General Squier, Chief Signal Officer, has contracted for the planting of large tracts of land in Texas and other Southern States in castor beans.

It has been found that highly refined oil made from this bean is the only lubricant which permits the air service to get 100 per cent efficiency out of the new Liberty motor.

One of the early problems developed by the powerful Liberty motor was that of finding a lubricant that would keep the bearings in perfect running order for a maximum of thirty hours.

Many tests were made with refined castor oil before it was developed to a point where it did the work satisfactorily.

Air Attack on American Troops in France

A half dozen bombs were dropped behind the American front recently in the sector northwest of Toul by German aeroplanes which were looking for ammunition dumps. They did not succeed in hitting any of their objectives, however, and none of the bombs dropped caused any casualties.

Groups of German bombarding aeroplanes, on the way to cities and towns far behind the lines, are passing over the American front almost continually. They are greeted by a hot anti-aircraft fire from the American batteries.

New York City Department of Education to Train Draft Men in Aero Repair Work

The Board of Education of New York City has started classes in repair work for the aviation service. The work is under the auspices of the Evening Schools, of which Henry E. Jenkins is in charge.

The men will be taught how to reproduce, repair and assemble various parts of the aeroplane. Only drafted men of Class I and 2 and who have had at least one year of experience in a mechanical trade necessary for aircraft work are qualified.

Ten classes to reproduce and repair the wooden parts necessary for an aeroplane have been organized. Two hundred and fifty men are taking this course. Six classes in engine repair work are now in operation, and we have also organized several classes in canvas work.

With the aid of the Eagle Aviation School, the Board of Education has had the use of several large skeleton aeroplanes and the services of Lieut. J. J. Lynch, who for two years served in the war zone with the British Aviation Corps, and of T. W. Gregory, both of whom are attached to the school.

$188,000,000 for Navy Aeronautics

Washington.—In continuing consideration, March 12, of the Naval Appropriation bill, the House Naval Committee increased an item of $94,000,000 for naval aviation to $188,000,000, and provided for an increase in the number of Marine Corps officers.

Group of authorities and officials responsible for the great success of the Official French Aerial Warfare Exhibit in New York. From left to right, top row: Major F. L. V. Hoppin, Military Aid to Governor Whitman; Lieutenant Henry Farré, the famous French painter-artist whose 140 wonderful paintings are part of the Exhibit; Honorable Gaston Siebert, French Counsul General; Governor Charles S. Whitman, of New York; Honorable André Tardieu, French High Commissioner; Commandant George Tulsane, in charge Aeronautic Division of the French Mission; Mrs. John Magee, member, and Mrs. William Astor Chanler, chairman of the Evecutive Committee. Second row: Mr. Alan R. Hawley, President Aero Club of America, member of the Executive Committee; Mrs. Benjamin Thaw, mother of Major William Thaw and Lieutenant Alexander Blair Thaw; Mrs. Walter E. Maynard, member of the Executive Committee; Mrs. Charles S. Whitman; Mrs. Edmund L. Baylies, member of the Executive Committee; Mr. Bernard H. Sandler. Lieutenant George Flachaire. French Air Service; Henry Woodhouse, member of the Executive Committee; Augustus Post, Secretary of the Aerial League of America.

10,000 Skilled Men Needed By the Aviation Section

The Signal Corps has authorized the following statement:

Ten thousand machinists, mechanics, chauffeurs, and other skilled workers are needed at once by the Aviation Section, Signal Corps.

The present call for 10,000 men is to fill an immediate need and may be regarded as the precursor of others as the service is being built up. Even at that the actual strength of the service to-day is over one hundred times what it was on April 1st last year.

The dependence of the Air Service on the most highly skilled men is being brought out more emphatically with every week of development. Where in the first rush there was little experience to indicate this fact, it has since developed that practically 98 men out of every 100 in the service must be skilled in some branch of work.

Aeroplane work has been wholly new and unfamiliar to American mechanics, who have been taken from other trades and converted hastily into workers on the most delicate kinds of jobs. It has been necessary for both officers and men to learn very largely by experience. At the same time a degree of care and attention not usually associated with American quantity, production, and methods has been required, as great watchfulness is essential to prevent any plane leaving the ground in imperfect condition.

Secretary Baker recently expressed this situation as follows:

"The great problem now remaining is to secure the thousands of skilled mechanics, engine men, motor repair men, wood and metal workers needed to keep the planes always in perfect condition. This great engineering and mechanical force at the aerodomes, flying fields, and repair depots, both here and behind the lines in France, is a vital industrial link in the chain of air supremacy. Without them the planes turned out would be useless and the flyers helpless."

Men registered in the draft may be inducted into this service by applying to their local draft board. Men not registered may enlist at any recruiting office. Further information may be had by applying to the air division, Personnel Department, Washington, D. C. In either case they will be sent to San Antonio, Tex., for segregation by trades, followed by a brief course of instruction at the flying fields or at various factories and organized into squadrons mostly for service over-seas.

The present call is especially for machinists, auto mechanics, engine repairmen, gunsmiths, chauffeurs, carpenters, blacksmiths, tinsmiths, cabinetmakers, electricians, coppersmiths, sheet-metal workers, propeller makers, wireless operators and constructors, tailors, tentmakers, sailmakers, truck masters, vulcanizers, welders, and makers, repairers, and installers of magnetos, ignition systems, cameras, watches and clocks, instruments, and typewriters.

No Contest of Liberty Motors

The Aircraft Board issued a denial that a contest between a Liberty aeroplane and an Avro aeroplane is planned. There will, however, be a series of flying tests at Dayton, in order to compare the Liberty and Rolls-Royce engines. Flights are also planned over Washington, but not in the nature of a contest.

Lieut. Francois Brach-Papa, Chief Pilot of the S. I. A. Co., of Turin, who holds notable altitude records.

Gifford to Speed Work on Aeroplanes

W. S. Gifford, Director of the Council of National Defence, has been appointed by the President, director of the Aircraft Board, and will devote much of his time to planning the production which the Aircraft Board will recommend to the Signal Corps.

Aero Squadron Organization in U. S. Army

While the Signal Corps is not giving out the exact organization of the Aero Squadron, the Army and Navy Journal publishes a tentative scheme, which outlines in a general way, the composition and organization of an Aero Squadron.

"The squadron consists of Headquarters, Flying, Supply and Engineer divisions. Its officers are a major, captain and fourteen lieutenants, and an enlisted personnel of approximately 140 men.

"The major is the commanding officer of the squadron, and it is not necessary that he should be a flier. He has an aid in the Headquarters Division, a lieutenant, who is in charge of all paper work, and who, in the absence of the major, takes command. The captain is in immediate command of the Flying Division, consisting of eleven lieutenants. He should be an expert flier and have a thorough knowledge of motors, planes and air currents. He designates the fliers for special duties and is responsible to the major for the planes.

"The Supply Division is in charge of a lieutenant, who must not only look after all supplies for the squadron, but must attend to the transportation. Under the lieutenant in charge of supplies there is a mess officer. The Engineer Division officers must be experts in repair of planes, cars, trucks and cycles. They must keep a report sheet of all men under them, and a memorandum of parts needed to replace stock used. The enlisted force is made up of a sergeant major, a first sergeant, photographer, chauffeur, three corporals, besides dispatch carriers, a motor truck driver and two privates. The supply section has two clerks, a truckmaster, his assistants, a mess sergeant, supply sergeant, mechanic, a corporal, cooks, ten privates (first class and privates) for general work. The enlisted men of the Engineering Section are four master signal electricians, four mechanicians (sergeants, first class) and five sergeants (second class), three corporals and three privates (first class). In the Flying Section of the squadron are one mechanician (sergeant, first class), one mechanician (sergeant, second class) for each two planes, six corporals (one for each two planes), twelve corporals (drivers of motor trucks) and four privates (second class).

"It is probable that there may be one or two more lieutenants than the number mentioned—at least one in the Engineer Division and perhaps two instead of one in the Supply Division. The full number of privates is not given. In addition to the planes there are motor trucks, an automobile for the headquarters, motor cycles, repair trucks, developing room for photographs, apparatus for signalling and other vehicles and devices."

Willard Re-elected Head of Council of National Defence

Re-election of Daniel Willard as chairman of the Advisory Commission of the Council of National Defence was announced recently.

W. S. Gifford and Grosvenor B. Clarkson will continue as director and secretary, respectively, of the commission and of the council.

Four Great Flying Camps Favored By Signal Corps

Division of the United States into four great aviation departments is under consideration by a council of Signal Corps officers, headed by Major General George O. Squier, chief signal officer.

The proposal most favored would result in the formation of an Eastern department to include the Northeastern and Eastern Military departments, with headquarters at Governor's Island; the Southeastern department, covering the territory now embraced in that military department, but with headquarters probably at Atlanta, instead of Charleston; the Southern, with headquarters at San Antonio, and the Central, embracing the Central and Western Military departments, with headquarters at Chicago.

A departmental aviation officer with rank of brigadier general would be placed in charge of each.

Navy Balloonist Has Thrilling Trip

Ablebodied Seaman Bell, U. S. N., of the dirigible balloon section of the Naval Air Squadron, stationed at Far Rockaway, L. I., naval air station, had an unexpected aerial journey a few days ago when he and twenty of his mates attempted to pull a big dirigible balloon to the ground after it had just completed its flight. The wind lifted the balloon into the air and pulled taut the ropes dangling from it. The strain was too much for the other seamen, who released their hold on the ropes, but Bell hung on until it was too late to let go with safety.

He was dragged into the air to a height of more than 500 feet, but he grimly held on to the rope. Before he let go, the big dirigible had raced more than a mile, and then the bag dropped to within a few feet of the ground. Bell jumped into a clump of bushes, receiving only a few bruises.

The navy dirigible was wrecked a few minutes later on the roof of a summer home. The balloon is one of the new patrol dirigibles, over 170 feet in length and a diameter of about 90 feet.

The airship could easily have been brought to the ground without damage by starting up the motors, but owing to the predicament of Seaman Bell the dirigible was permitted to drift, in order to avoid cutting the rope on which Bell was hanging for his life.

"Ballads from Barracks C"

Sergeant Rusti Conn, at present Barracks Sergeant at the Ground School at the University of California, is publishing a volume of aeronautic verse entitled "Ballads from Barracks C." He describes the life of a Flying Cadet and pictures the events that take place at the ground school and the flying field. Sergeant Conn was formerly press agent for Barnum and Bailey.

More Aviation Training Fields

The War Department has authorized the establishment of aviation training camps at Americus, Ga.; West Point, Miss., and Sacramento, Cal. The newly authorized camps will be made what are known as one unit camps, and four squadrons of the Aviation Section will be trained at each of the camps. Several other sites have also been recommended and await the approval of the General Staff and the Secretary of War.

Automobile Output Curbed

One of the first official acts of Bernard M. Baruch, newly appointed head of the War Industries Board, was to issue a request to the motor car industries to cut down their production of pleasure cars fifty per cent., in order to increase the materials and supplies needed for war purposes. Measures are in progress to curtail the use of brick and coal for non-essential purposes.

The policy of the War Industries Board, as outlined by an authority, will be, however, to effect its measures of conservation and priority with the least possible dislocation or shock to industry in general.

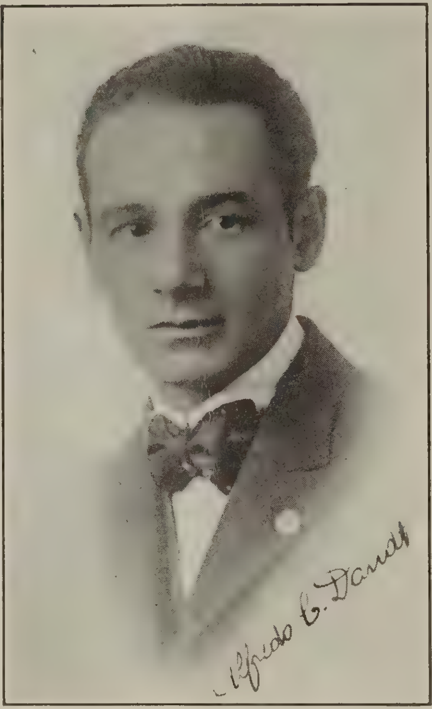
The order affecting the motor car industries is said to be largely actuated by a realization of increasing the output of aeroplane and tank motors.

Lieut. Flachaire to Aid Overseas Hospital

The Mayor's Committee on National Defence of New York City will aid the women's overseas hospital in their grand military and naval meet, to be held on the afternoons and evenings of March 15, 16 and 17th, at Madison Square Garden. In connection with this event, Lieutenant Flachaire of the French Aviation Corps has promised to fly over the city dropping circulars with appeals for the cause. Arrangements are being made to take passengers for flights at $50 per trip.

Aeronautic School at Carnegie Institute

An aeronautic school to be called the Langley Laboratory of Aeronautics will be erected in the near future at the Carnegie Institute of Technogolgy at Pittsburgh. It is expected that the building will be completed in thirty days.



Alfredo C. Dandt, an enthusiastic supporter of aviation in South America.

American Training Schedule Severe

The training schedule now in force at the Signal Corps Aviation Schools required each student to fly nine hours with an instructor before he is allowed to do "solo work." This compares with the four-hour schedule maintained under the regulations of one of the Allies, on whose training system ours has been largely based. The American flying fields to date have had one accident to approximately every 2,400 flight hours against one in every 1,400 in the flying schools of that country.

Rules for Rating of Military Aviators Adopted

Recent regulations of the War Department provide for the rating of reserve military aviators as junior military aviators, and military aviators after a prescribed period of service or for distinguished service upon the recommendation of the commander in charge.

According to these regulations, officers of the Signal Reserve Corps and those temporarily commissioned, who have passed the Reserve Military Aviator test will not be rated as Junior Military Aviators for six months as reserve aviators in the United States, or have served three months as reserve aviators on on active service in time of war, or four months at training stations and two on war duty, unless recommended for distinguished service.

Leaping from Captive Balloon Thrills American Aviator

Six successful leaps from captive balloons are to the credit of an American aeronaut now in London for recuperation after months of active service with the British armies in France. In only one of these perilous and thrilling exploits was the man injured. On this occasion while falling sideways strapped to his parachute, which moved with a stiff wind, his feet caught in the ruins of a shell-wrecked mill, and the muscles of his side were seriously strained before he could get himself loose.

"Tell me about it," said a correspondent for the N. Y. *Globe*. "Are these leaps from balloons thousands of feet up exhilarating?"

The American officer smiled dryly and placed his hand against his injured side.

"They give you some thrill, right enough," said he. "My most pronounced sensation in all my leaps has been that of joy at escaping my Hun assailant or assailants. It is simply immense to find yourself alive and shooting earthward, particularly if toward the rear of your own lines, after machine gun bullets and the flaming balloon have seemed to make your life worth not a second's purchase.

"My latest leap—I hope it may be my last, but probably it won't was into a gale that had been buffeting me for a couple of hours. Indeed, it had made my head ache. It had also slightly numbed my faculties. But for the wind everything was serene. There were some fat clouds about, but no hum of aeroplane. I don't know just how it happened, but before I knew it a Hun airman was pitching straight down at me from the top of a cloud. His machine gun sputtered fiercely as he came. I was not hit, but all at once he got in a fire shell and the balloon burst into flames.

"Then I dipped over the edge of the basket and jumped. Being an old hand at the game I knew how to counteract the effects of the long fall before the parachute opens. I learned this while in those swift dropping New York elevators. At the instant of falling I fill my lungs with all the air I can hold. This fortifies me against the peculiar and powerful upward pressure of the air during the first stone-like fall of some hundreds of feet.

"It was a good job that I dropped fast this time, for that Hun was right after me, shooting as fast as he could. I think I fell 1,000 feet before my parachute took any notice. Then it opened with great suddenness and away I went obliquely through the air at express-train speed. Of course I could not pick a place to land. No man can. When I felt my feet catching in the ragged walls of the building I got out my sheath knife as quickly as possible and cut myself loose. When some of my pals reached me I was quite comfortable. I knew nothing."

Inter-Allied Conference on Standards in London

The Aircraft Board has issued the following statement:

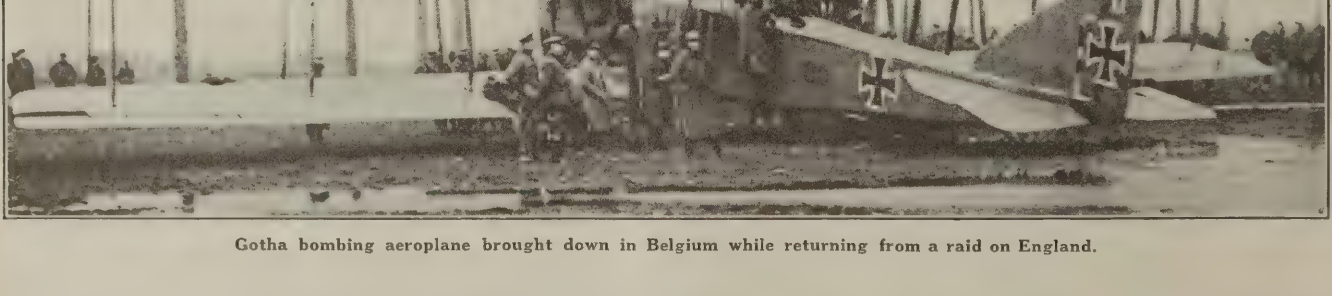
The arrival in England is announced of delegates from all the allied countries for conference on international standards, at which a standardization of manufacturing materials as related to the production of machinery, motors, aircraft, etc., will be considered.

The American delegation, headed by F. G. Diffen for the aircraft board, includes members from all the prominent engineering societies of the country—the Society of Automotive Engineers, the American Society of Mechanical Engineers, the American Society of Testing Materials, etc. There are also members from the Aircraft Board, the Advisory Committee for Aeronautics, the Signal Corps, the Navy, and the original International Aircraft Standards Board, from which this conference is an outgrowth.

The purpose of this inter-allied meeting, which is the result of the efforts of Mr. Diffen, is to enable better industrial service to be given with less man-hour effort, through relieving plants from carrying in stock unstandard materials, for which there is small call, and concentrating on materials of know performance for the same work.

No attempt will be made by the conference to standardize aeroplane construction, but rather those materials and units only which are at present causing confusion in purchase and delivery and for which suitable standards can be established.

The following is the list of the American members: F. G. Diffen (chairman), Dr. W. F. Durand, Lieut. Commander Benjamin Briscoe,



Gotha bombing aeroplane brought down in Belgium while returning from a raid on England.

With the American Air Forces "Over There"

David E. Putnam, a direct descendant of Israel Putnam, has just brought down his third German aeroplane within a month on the French battle front. He is the nineteen-year-old son of Frederick H. Putnam of Boston and Newton. In a letter received by his mother yesterday, he says:

"We had been flying about ten minutes when I looked back and saw two machines headed out of Germany. Down on the nearer one I came, my gun throwing out a spray of lead. But when I had fired about fifty shots he got under me, and I shot by toward plane No. 2, leaving No. 1 for our men behind me. No. 2 dived, but I followed, always shooting. We had come down from 12,000 feet to 3,000 in less time than it takes to tell it, when suddenly the machine in front wavered and then plunged straight down. It was a 'rumpler' biplane. Oh, I am proud!"

Vernon Booth of Chicago, of the Lafayette Corps, brought down a German aeroplane in a fight several miles inside the German line. Booth was on patrol duty when he sighted his adversary, in a two-seated machine, and attacked him at a height of a mile. Several rounds were exchanged, and soon the German began to descend. Booth followed the hostile aeroplane down until it fell into a forest just inside the German lines.

A N. Y. "Times" correspondent writes that American army aviators in France are doing good work, using ten French Briguet machines in daily flights over the German lines. Several combats took place in the course of a week, one enemy machine being brought down in a wood near a field hospital. Four Zeppelins passed on one day recently, going toward the Swiss frontier. Our officers at the aviation camp believe that the army should adopt the three best types of allied machines and improve upon them.

A "Globe" correspondent in Paris describes the office of the American Air Service in a recent despatch to his newspaper. A modern seven story apartment house has been requisitioned for this purpose.

There are about 1,000 persons working in this building, through which much of the business of the air service passes, although it is not the air service staff headquarters. All are on duty from 9 A. M. until 12.30 P. M., off for an hour or an hour and a half at the most for the midday meal, after which work goes on steadily until 6 P. M.

On each floor is a French soldier to direct visitors who do not speak English. In each apartment is a separate section of the service —instruction, material and others, from the first floor to the sixth.

Vernon Booth, of the Lafayette Flying Corps, brought down his first Boche machine. Booth was a very popular member of the Harvard Club of New York, where he has resided since 1913, up to his departure for France, practising law.

Cadet Joseph F. Stillman, a Yale graduate, was killed in a collision while training in England. Stillman won distinction as a football player and in rowing.

An interesting trophy of the British Western front—the fuselage of a German chaser. British Official Photo.

Curtis Seam Read, also of Yale, one of the first to volunteer in the Yale Hydro-Aeroplane Unit, was the victim of a hydro-aeroplane accident in France. Read was one of the most popular members of his class.

Personal Paragraphs

N. J. Clausen has joined the Curtiss Engineering Corporation, Garden City, N. Y. He formerly was a draftsman with the Otis Elevator Co.

M. L. Heminway, formerly sales manager of the Davidson Rubber Co. of Boston, has been appointed secretary of the War Service Committee of the Rubber Industry of the U. S. A.

Harry Newman, a motor car distributor of Chicago, has arranged to sell aircraft as well as road craft. He is the first motor car dealer to handle aircraft on a commercial basis.

Donald W. Douglas, formerly aeronautical engineer, Aviation Section, Signal Corps, Washington, is now chief engineer, Glenn L. Martin Co., Cleveland.

John J. Rooney, formerly at New York, is now aeronautic engineer, Briggs Aeroplane Co., Alexandria, Va.

Joseph A. Steinmetz, president of the Aero Club of Pennsylvania, is one of the directors of the new Y. M. C. A. School of Aeroplane Construction which has recently been started at 717 North Broad Street, Philadelphia. The purpose of this school is to assist in the aircraft production program by developing skilled labor that can be utilized in factories throughout the country.

The engagement of Miss Dorothy Van Winkle to Harry V. Moser, a cadet at Love Field, Dallas, Texas, was announced recently. Moser graduated from the School of Military Aeronautics at Princeton.

Experts Design New Air Bullet

Washington.—The War Department has made public the announcement that the ordnance bureau has developed bullets of three types for use of aeroplane fighters which equal in qualities anything which our allies or the Germans have produced.

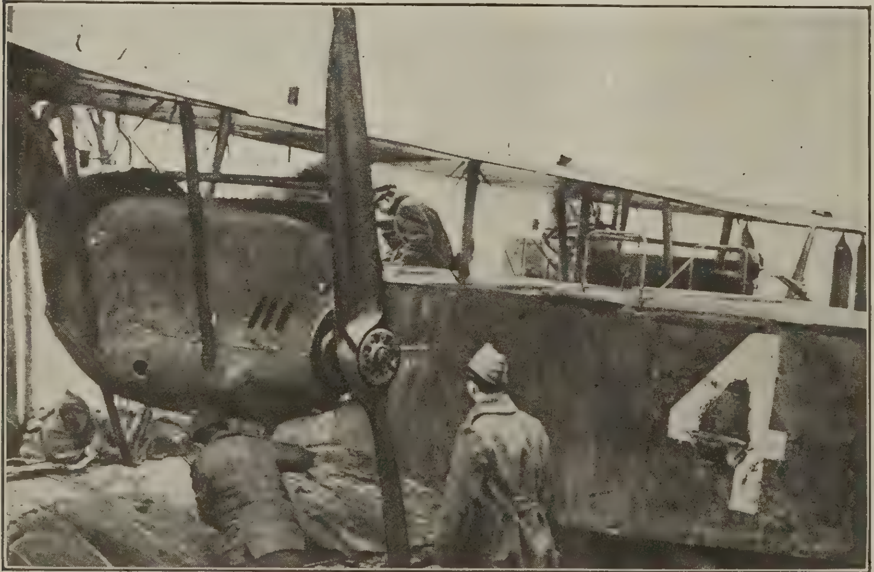
"The present war brought forth a new kind of ammunition for aeroplane use in the form of special cartridges containing bullets for armor piercing, tracing and incendiary purposes," said the statement.

"With the progress the more military parts of the aeroplane were protected with light armor, so that it became necessary to introduce the armor piercing bullet.

"As the gasoline tanks were particularly susceptible to incendiary explosion. It was necessary to procure a bullet containing an inflammable substance, ignited upon discharge, which would carry the spark or flame into the tank upon piercing it.

'As the target (the enemy aeroplane) was within fighting range for only brief moments at a time and as there were no means of determining the fire effect as on land, a tracer bullet containing a bright burning composition which would indicate the path of the bullet in daylight as well as darkness, and thereby allow the aim of the machine gun to be corrected, was introduced. The composition is set on fire upon discharge and the bullet flies through the air as a bright spark, plainly visible to the machine gun operator."

In addition to the three distinct types of bullets the ordnance experts have developed combinations of the ignition of the tracer bullets with the armor piercing heads which are regarded as remarkable accomplishments in view of the fact that the diameter of these projectiles is only 3-10 of an inch.



The engine housing on the German Gotha brought down recently in Belgium. French Official Photo.

Cotton Approved for 'Plane Wings

Washington.—Official denial that the government has been placing orders for silk for use in the manufacture of aeroplane wings has been issued by the Aircraft Production Board. Rumors that heavy purchases of silk were contemplated have been circulated and many offers have come to the purchasing department from manufacturers whose material was said to be satisfactory for aeroplane purposes.

It is true, however, that silk has been considered. In fact, all fabrics have been experimented with, and the Bureau of Standards has been working under the supervision of the Aircraft Production Board, endeavoring to find the best material for wings. In addition, many experiments are being made by private individuals and manufacturers.

Before the war linen was used exclusively for aeroplane wings, but since the conflict broke out the availability of flax has been materially lessened and it was necessary to find a substitute. England, France and Italy used all the linen produced within their borders, and it was placed under an embargo early in the war.

The enemy countries had the advantage of obtaining flax produced in conquered Belgium. The linen that could be spared by the allies was not nearly enough to keep up with the ambitious air programme of the United States.

Linen wings were treated with acetone "dope," to make the fabric taut, non-inflammable and strong, and also to keep it from splitting and tearing when the wings were riddled with shrapnel. Silk, it was found, would not take this "dope," and the same is true of many other fabrics. The most severe tests were imposed on all fabrics, it being necessary to subject them to conditions stimulating as nearly as possible actual war conditions —twisting, turning and explosive and incendiary bullets.

Out of all the fabrics placed under these tests cotton proved to be the most satisfactory. A new way of spinning this material was devised and this method is closely guarded as a valuable military secret. Roughly compared with the usual process of cloth production, its description is covered by the term "spinning backward."

This new process cotton is said to surpass the stoutest linen and has passed the most rigid tests. Early experimenters thought it had an admixture of linen, but when unraveled it was found to be "pure cotton." It is understood the fabric has worked out so satisfactorily that the British Government has ordered several million yards for aeroplane purposes. It has also been found to be desirable for tentage.

New Type of Coupling Overcomes Rattle and Back Lash

A newly designed coupling, adaptable to all magnetos, generator or pump shaft drives, is similar in construction to the Oldham type, excepting that it has an automatic spring take-up for wear and to prevent noise.

The center piece consists of a ring two inches with $\frac{3}{32}$" wall and riveted solidly to the inside of this ring are two triangular shaped steel blocks; (these rivets however do not carry any load).

Placed midway between these two solid blocks are two similarly shaped blocks loosely riveted and are impelled inwardly by means of small coil springs. Regularly constructed shaft end members, each with two projections or jaws opposite each other, are inserted between the blocks, thus forcing the loose blocks outwardly from their inner rivet heads by deflecting the springs.

Due to spring pressure these loose blocks hug the jaws at all times and will take up any wear that takes place. This squeezing action of the loose blocks does away of course with all looseness, rattle and back lash. The drive is meant to be taken on the solid blocks, but the spring tension is such that the loose blocks withstand a pressure of 34 pounds before they will squeeze outwardly.

About twenty-five of the largest motor car, truck and motor manufacturers have been testing this coupling, which is manufactured by G. D. Bailey Co. of Chicago, for several months with satisfactory results in every case and several good sized contracts have already been made and many more will be closed in the next few months. Allowance is made for $\frac{1}{32}$" wear, but many tests covering from 25,000 to 30,000 miles have shown a wear of less than .005.

CDT—Report to Aviation Concentration Camp, Dallas, Texas.
CGC—Report to Aviation Concentration Camp, Garden City, L. I., N. Y.
CGS—Report to Aviation Concentration Camp, Greenville, S. C.
CLR—Commissioned as Colonel, Aviation Section, Signal Reserve Corps.
CMV—Report to Aviation Concentration Camp, Morrison, Va.
COL—Commissioned as Colonel, Aviation Section, Signal Corps.
CPR—Commissioned as Captain, Aviation Section, Signal Reserve Corps.
CSO—Report to the Chief Signal Officer, Washington, D. C.
CUI—Report to School of Military Aeronautics, Cornell University, Ithaca, N. Y.
CWT—Report to Call Field, Wichita Falls, Texas
DAF—Report to Door Field, Arcadia, Fla.
DIS—Honorably discharged from service.
EEP—Report to Essington Field, Essington, Pa.
EHT—Report to Ellington Field, Houston, Tex.
ELA—Report to Eberts Field, Loanoke, Ark.
FLR—Commissioned as First Lieutenant, Aviation Section, Signal Reserve Corps.
FLT—Commissioned as First Lieutenant, Aviation Section, Signal Corps.
FOB—Report to Fort Omaha Balloon School, Omaha, Neb.
FRF—On duty requiring regular and frequent aerial flights.
FSO—Report to Fort Sill School for Aerial Observers, Fort Sill, Okla.
GIT—Report to School of Military Aeronautics, Georgia Institute of Technology, Augusta, Ga.
GLC—Report to Gerstner Field, Lake Charles, La.
HHN—Report to Hazelhurst Field, Mineola, L. I., N. Y.
JHU—Report to School of Military Aeronautics, John Hopkins University, Baltimore, Md.
KST—Report to Kelly Field, So. San Antonio, Tex. (When specified in the order, the number of the field is given in parantheses)
LDT—Report to Love Field, Dallas, Tex.
LHV—Report to Langley Field, Hampton, Va.
LTC—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Corps.
LTR—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Reserve Corps.
MAJ—Commissioned as Major, Aviation Section, Signal Corps.
MDO—Report to McCook Field, Dayton, Ohio.
MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MMP—Report to Middletown Aviation Supply Warehouse, Middletown, Pa.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
REL—Relieved from active duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRC—Report to Riverside Field, Riverside, Cal.
RRV—Report to Richmond Aviation School, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
THT—Report to Taliafero Field, Hicks, Tex. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WDO—Report to Wilbur Wright Field, Dayton, Ohio.

Note 1. Report to Signal Corps Camp, Dallas, Tex.

Note 2. Report to district manager of inspection, 870 Woodward Ave., Detroit, Mich.

Note 3. Report to Pawtucket, R. I.

Note 4. Report to commanding officer, 309th Cavalry, N. A., Fort Sam Houston, Tex.

Note 5. Report to New Haven, Conn.

Note 6. Report to Chicago, Ill.

Note 7. Report to School for Radio Mechanics, Carnegie Institute of Technology, Pittsburgh, Pa.

Note 8. Report to headquarters, Southern Department, as aeronautical officer of that department.

Note 9. Report to commanding officer, training section, air division, Washington, D. C.

Note 10. Report in person to the Secretary of War.

Note 11. Report to Signal Corps Troops, Arcadia, Fla.

Note 12. Report to Major C. M. Hall, equipment division, Dayton, O.

Note 13. Report to Riverbank Laboratory, Geneva, Ill.

Note 14. Report at Dayton, Ohio.

Note 15. Report with detachment of seven enlisted men of 501st Aero Construction Squadron.

Note 16. Report at Camp Dick, Dallas, Texas.

Note 17. Report to Chief of Staff.

Note 18. Report to District Inspection Manager, 870 Woodward Ave., Detroit, Mich.

Note 19. Take station at Rochester, N. Y.

Report 20. Report at Army and Navy General Hospital, Hot Springs, Arkansas, for treatment.

Note 21. Report to Lieut. Col. Virginius E. Clark.

Note 22. Take station at New York City.

Note 23. Report to Aviation Mechanics' Training School.

Note 24. Report to Maj. H. L. Shepler, plane production section, Cleveland, Ohio.

Note 25. Report to District Manager of Inspection at Pittsburgh, Pa.

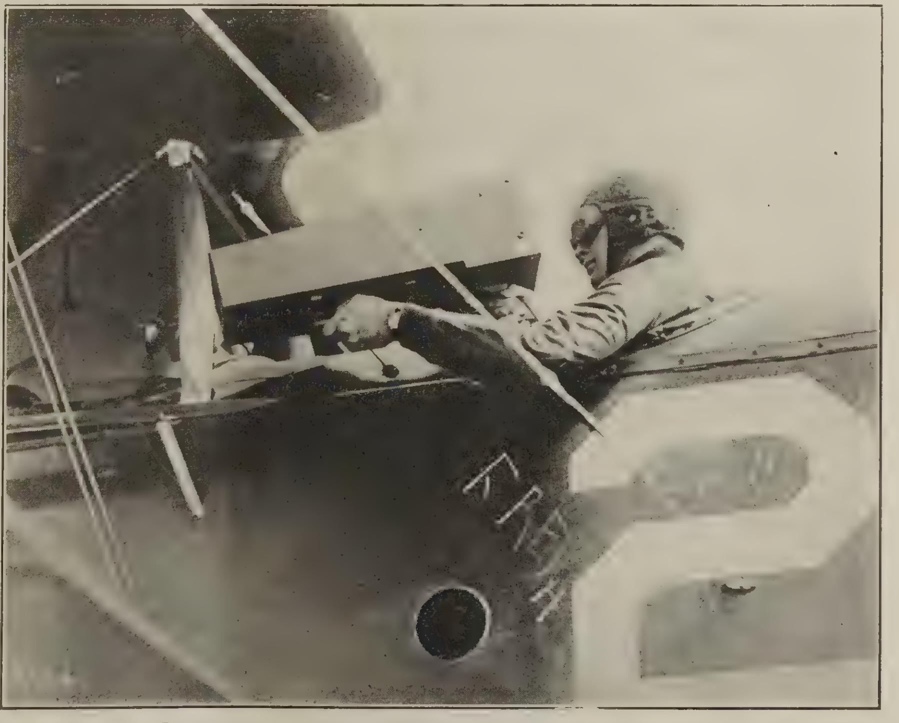
Erecting a wooden hangar, reinforced by metal joints, in France



An aeroplane graflex camera is a simple and efficient instrument upon which a large measure of the accuracy of artillery fire depends

CHARACTERISTICS OF THE LEADING AMERICAN AEROPLANES, HYDRO-AEROPLANES, AND FLYING BOATS, 1917-1918

AS a historical record AERIAL AGE takes pleasure this week in presenting a series of tables and diagrams showing the characteristics of the leading American aeroplanes, hydro-aeroplanes, flying boats and aero-motors. Naturally the censorship consequent upon military developments makes it undesirable to present in any form information which would be valuable to the enemy, and therefore the diagrams present only those machines which the Committee on Public Information have permitted us to illustrate during the past year.

AMERICAN AEROPLANES 1917-1918

EVERY MILITARY AVIATOR OUGHT TO KNOW WHAT HIS OWN AND THE ENEMY'S MACHINE CAN DO AND HOW THEY LOOK

By HENRY WOODHOUSE

Author of the "Text-book on Naval Aeronautics", "Text-book on Military Aeronautics", etc.

"IF you see an aeroplane that does not look like any of the machines shown in this leaflet, you are to make every effort to bring it down."

This, in effect, is the instruction that every French and Italian aviator receives, not only while he is being instructed, but periodically, whether he is at one of the permanent military aerodromes or temporarily stationed on the fronts.

The Allied Governments found it necessary to teach their aviators and students all about their own machines, and as much as possible about the enemy's machines, particularly their appearance. As a basic principle, the aviator is taught that what does not look like one of the Allied machines must be an enemy machine. Therefore, every effort should be made to bring it down.

The anti-aircraft forces are taught the same thing, and that knowledge of the features of the different types of aeroplanes is one of the prime factors in making the anti-aircraft forces efficient.

Lacking that knowledge, both the Allied air forces as well as the anti-aircraft defenses, get confused and permit the enemy to get temporary advantages, which cost the lives of Allied aviators, as well as of the population of the cities which are raided—without mentioning the strategic advantages which the enemy gains through gathering information or surprising the Allies.

It has also been found of extreme importance to have every aviator know what the enemy's machines, as well as one's own machines, can do. It will be recalled that when the first Spad appeared, the German aviators did not give it credit for the speed which it had, so they ventured too much and too far for their own good. The Cicogne Squadron, and the Lafayette Squadron were enabled thereby to maintain supremacy in the air and bring down a number of German aviators, who did not know the fighting characteristics of the Spad.

Unfortunately, the same thing was true when the Germans brought out the Fokker monoplane. For several weeks, before the Allied aviators could be taught the characteristics of the Fokker, the German aviators brought down a number of Allied aviators.

The same was true in the case of the various Sopwith combat machines—and it is true of every new and more efficient type of machine.

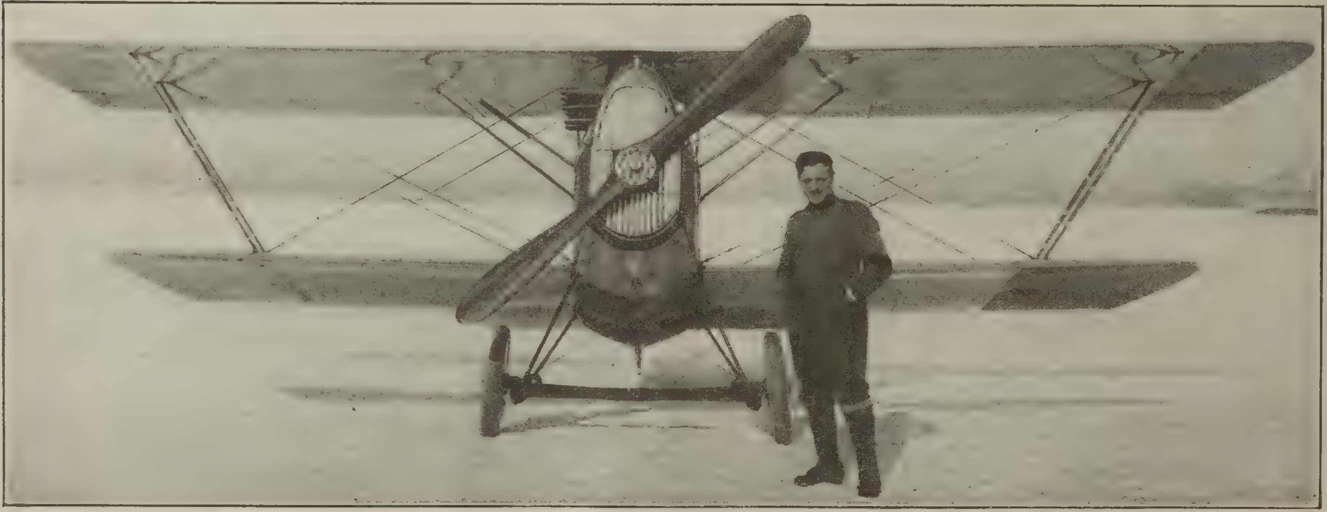
It has also been true in the case of the large bombing machines. Lack of knowledge of their characteristics resulted in many surprises.

In some cases some of the machines which were thought to have "blind sides" were found to have guns mounted in front and rear, and to shoot below as well. An aviator in a single seater fighter would attack what appeared to be a "pusher type," and all at once, a gunner would emerge from the small cock-pit and turn a stream of fire on him.

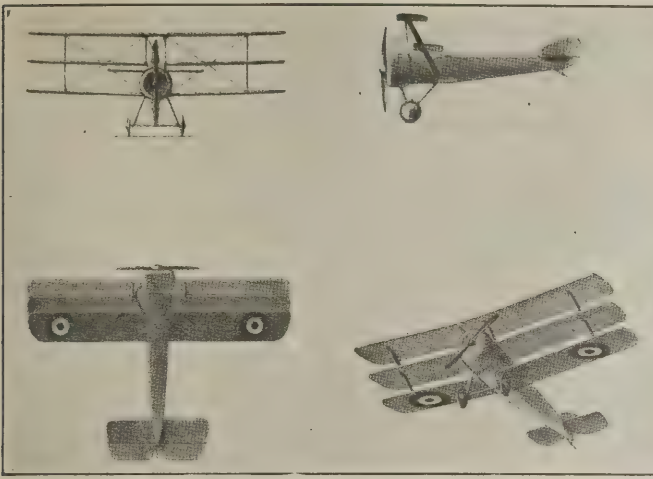
That was also true at the time when the Gothas first came out with the arrangement to shoot below, from the rear. That was an unpleasant surprise to the Allied aviators who attacked them from the rear.

The United States is to train thousands of aviators, observers, aerial photographers and anti-aircraft gunners. Many are taking their preliminary course and thousands are waiting their turns. Thousands more of prospective candidates are not yet of age or have passed the draft age and will volunteer as they learn more about military aeronautics. Military and aeronautic authorities agree that AERIAL AGE can render a valuable service to the nation, by continuing to publish descriptions of machines used by the enemy, as well as by the Allies. In the last case it is necessary, of course, not to publish details of machines which the enemy has not yet captured, or to give details of performances of newly adopted types. In a general way, any type that has not been used in number at the fronts for a period of at least two months must be considered as new and details of performances must not be published.

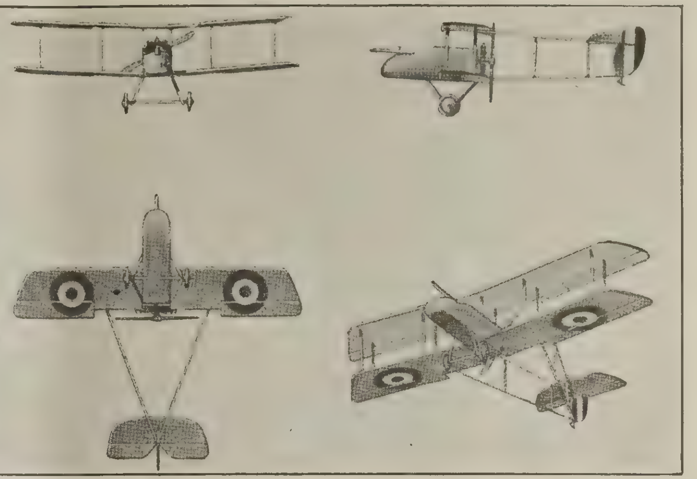
The publication of details of German machines is encouraged: The Boche knows, of course, all about their own types; it also knows how the Allied aeroplanes look as soon as one or two are captured. But it does not always know all about its performances. Therefore, information about performances of new types should be withheld.



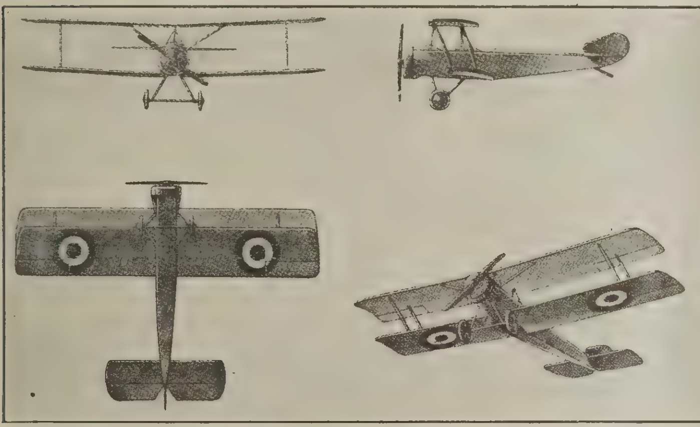
The Pomilio combat plane, said to be the fastest battleplane in existence. (Official Italian Photo.)



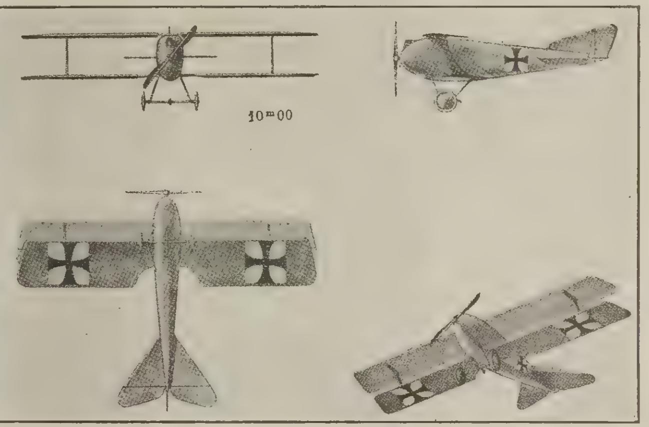
Sopwith Triplane (British). The motor, a rotary Clerget, is completely surrounded by an aluminum cowling. The planes are equal in span, very narrow in chord, and braced by a single strut at either side of the fuselage. Planes highly staggered. Ailerons on all three planes. The only European scout triplane. Said to be very fast



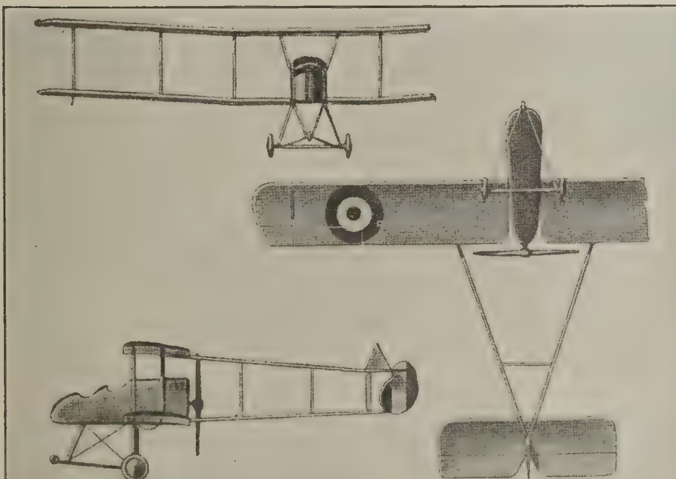
De Havilland 2 (British). Somewhat resembles the F. E. 8, but the outriggers meet one another at the vertical rudder instead of at the tail plane. The small fixed vertical fin, together with the vertical rudder, gives the appearance of a bird's head and beak. A rotary Monosoupape Gnome engine is placed at the rear



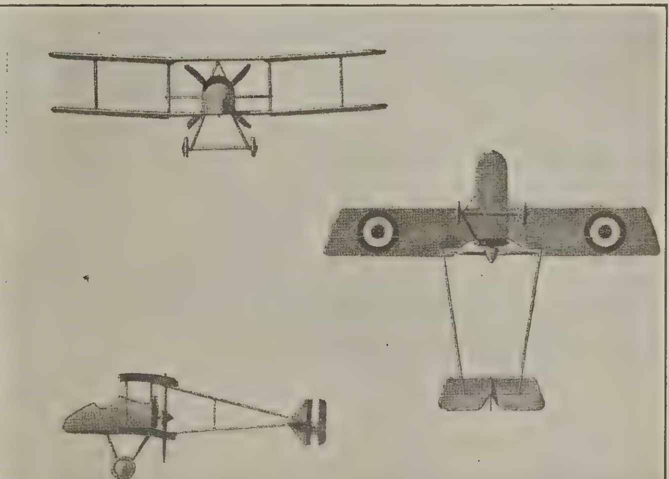
Sopwith single-seater (British). Used by the French and British. Also the Sopwith two seater. Equipped with a rotary engine, Clerget or Rhone. Identified by the central set of struts which stagger outward at the upper end. The fixed triangular fin is rounded off at its leading end. Planes are considerably staggered. Ailerons on both upper and lower planes



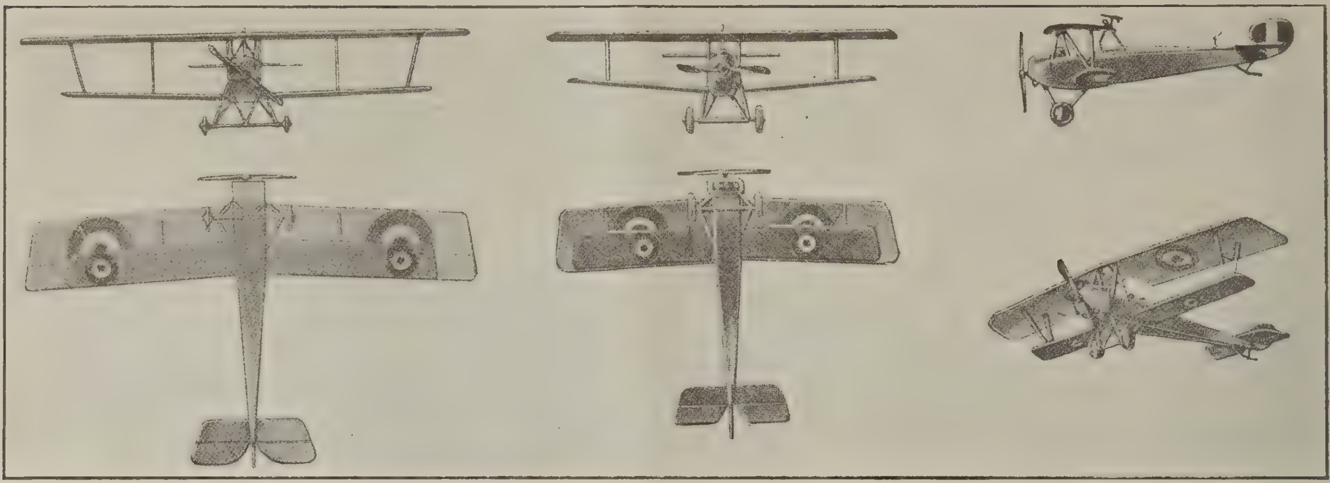
Roland two-seater (German). The engine is a fixed Mercedes, 175 H.P. A machine gun and bombs are carried. The body is exceptionally deep, reaching as high as the upper plane. Windows are provided in the sides of the fuselage for observation. There is but a single interplane strut at either side of the body. Planes are considerably staggered. Fin and rudder placed very high



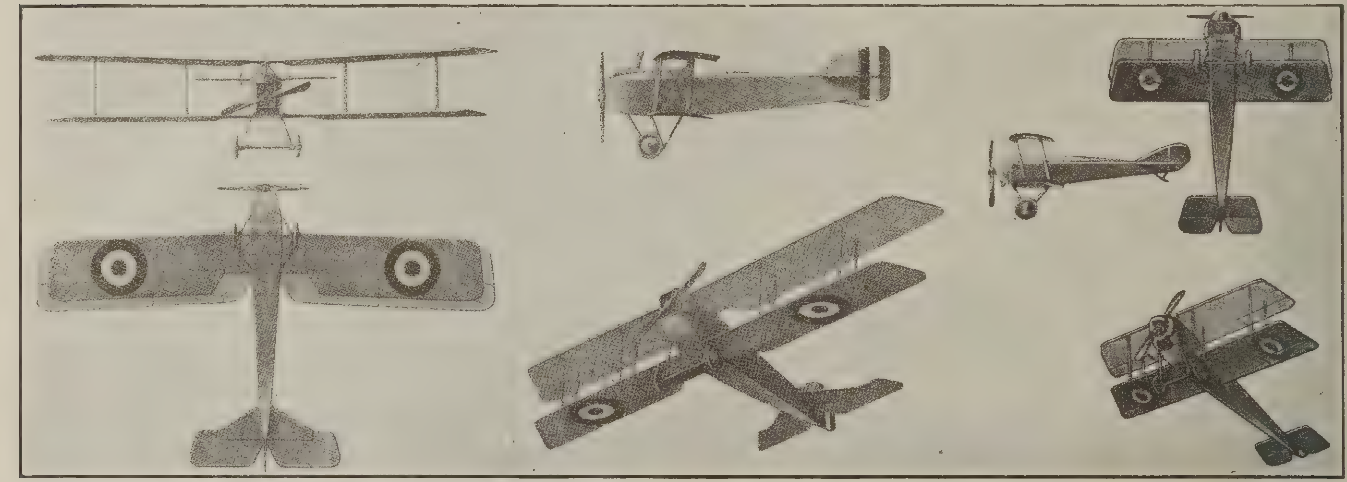
F. E. 2b and 2d (British) (Farman Experimental). Pusher type with a nacelle which carries a fixed Beardmore or Rolls Royce engine. Empennage carried on four outriggers. Landing gear consists of two main wheels and two smaller auxiliary wheels below the forward cock



F. E. 8 (British). Scout type single seater pushr with a rotary Monosoupape-Gnome engine. Fin and rudder area similarly disposed above and below the tail plane. Two wheel landing gear and tail skid below the fin. A movable Lewis machine gun is carried on the deck of the nacelle

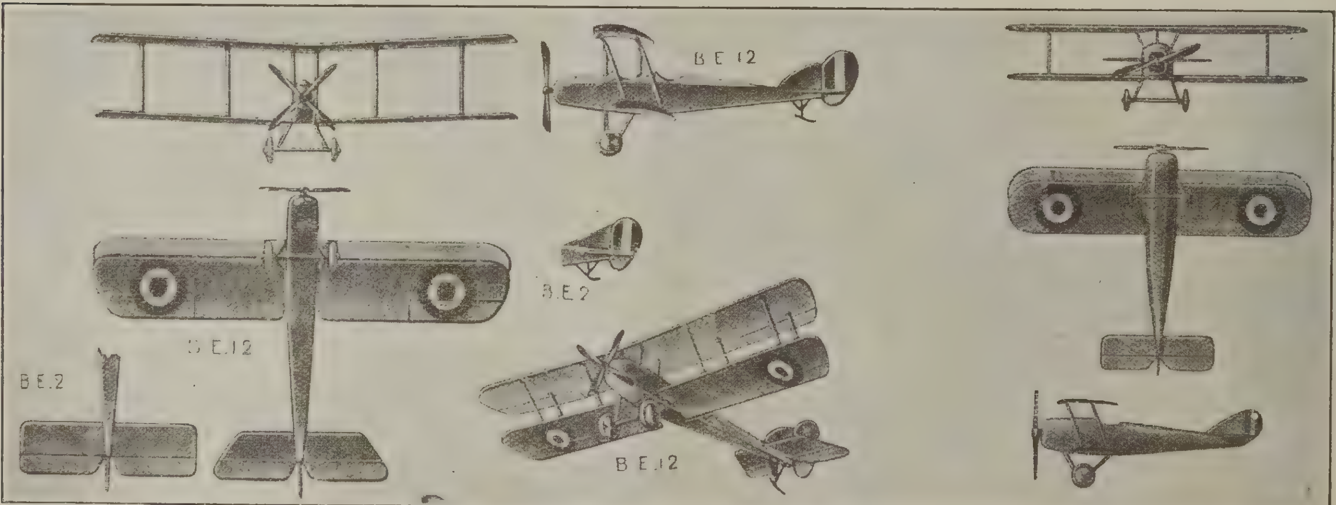


Nieuport. Used by the French, British, Belgians and Italians. Made in single-seater scouts which have rotary Rhone or Clerget engines and having a small wing span, and also two-seaters with fixed Hispano-Suiza engines and a larger wing span. Struts between the planes are V shaped. Two-seaters have two sets of struts at either side, the outer sets inclined outward at the top. Other struts are vertical. The Nieuports are fitted with a belt-fed Vickers machine gun fixed on the fuselage, and a movable Lewis gun mounted on the upper plane. Some of the single-seaters are provided with two Lewis guns in addition to the Vickers



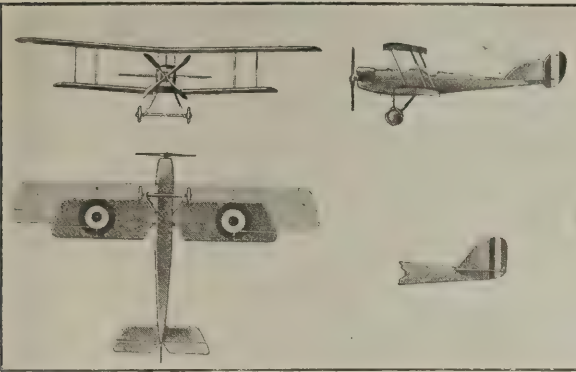
Bréguet Av. (French). Has a fixed Renault engine. Uses a gun firing forward, attached to a strut at the left of the fuselage, and a gun at the rear cockpit. Dihedral on the upper plane only. There are ailerons on the upper and lower planes, the lower ones being exceptionally long and extending from the wing tip nearly to the body. The elevators are balanced

Bristol Scout (British). Called the "bullet". One of the fastest scouts. Uses a rotary Rhone engine. There is also a Bristol two-seater which has 2 pairs of struts at either side of the body. The two-seater is equipped with a fixed engine

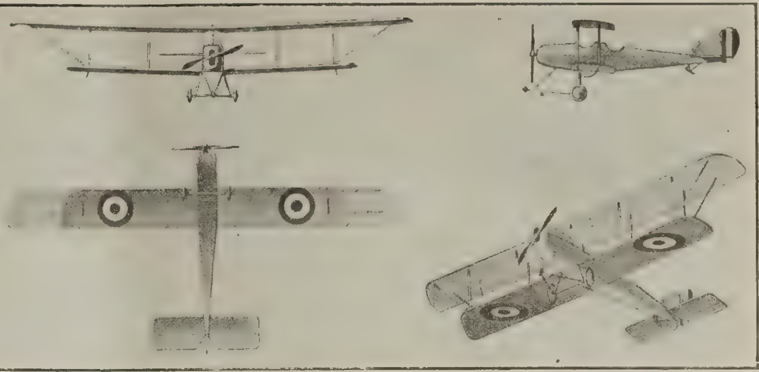


B. E. 2c and the B. E. 12 (British) (Bleriot Experimental). These machines are equipped with fixed R. A. F. (Royal Aircraft Factory) engines with a four-bladed propeller. The planes are staggered and have a pronounced dihedral on both planes

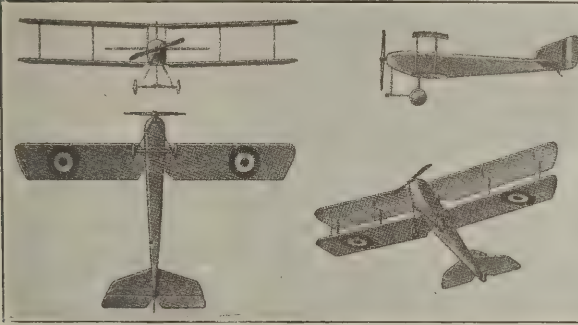
Vickers Scout (British). Rotary Clerget engine. Single pair of struts at either side of the body. Planes equal in area and similar in outline. High stagger. The engine is completely surrounded by an aluminum cowling



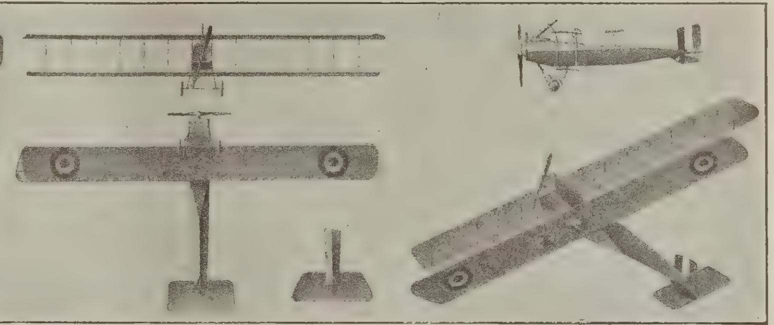
B. E. 2e and R. E. 8 (British). The B. E. 2e has a Hispano-Suiza engine and the R. E. 8 has an R. A. F. engine. There is a single pair of struts at either side of the body, in addition to one strut which connects each pair of ailerons on upper and lower wings



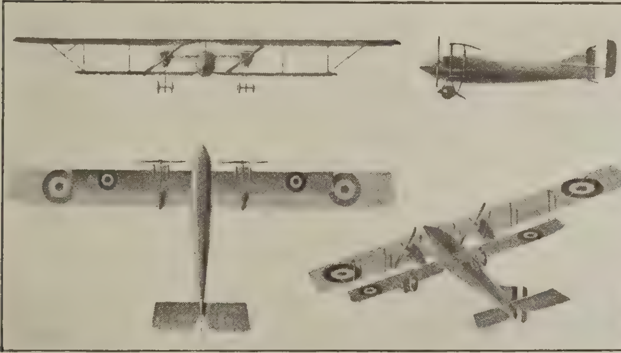
R. E. 7 (Reconnaissance Experimental) (British). Upper plane of greater span than the lower. Two pairs of vertical struts at either side of the body and a pair of inclined struts which carry the overhang. A fixed R. A. F. (Royal Aircraft Factory) engine is used



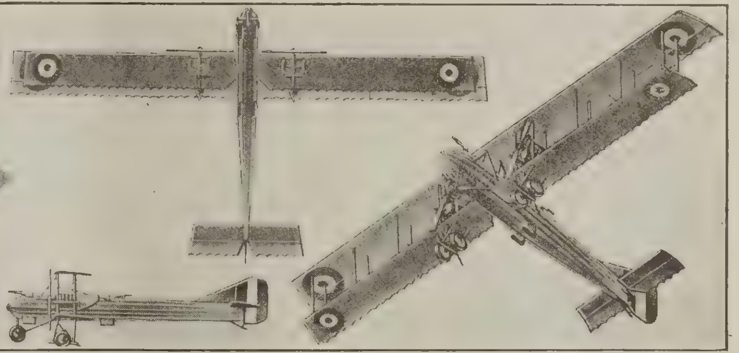
Armstrong-Witworth (British). The engine is a Beardmore. Upper and lower planes are practically similar in shape. They are not staggered nor swept back and have but a little dihedral. Two sets of struts at either side of the fuselage. The fin surface is rather large and carries the rudder quite high. Three wheels are used in the landing chassis



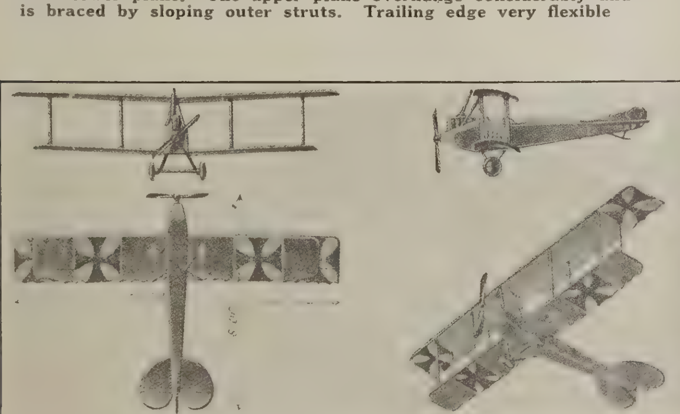
Paul Schmitt (French). Made in two types, the type B. R. A. H. (Bombardment Renault, Ailes hautes) and the B. R. A. B. (Ailes basses). A fixed Renault engine is used, provided with a silencer. The planes of this machine are arranged to be altered while the machine is in flight, changing the angle of incidence according to the lift required. An unusually large number of interplane struts used



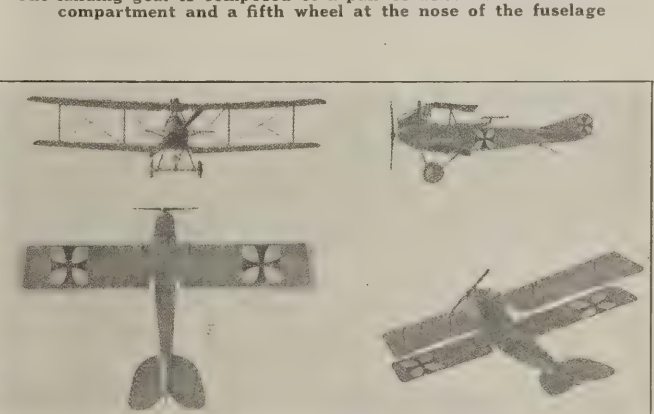
Caudron G.6 (French). Quite similar to the R. 4, but 2 rotary Rhone engines are used. It has only four landing wheels and a very narrow lower plane. The upper plane overhangs considerably and is braced by sloping outer struts. Trailing edge very flexible



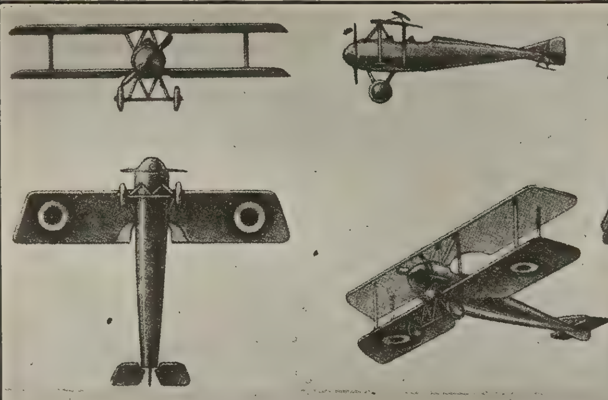
Caudron R. 4. Used by the French and British. Twin motored tractor type with a fuselage. Hispano-Suiza or Renault engines used. The landing gear is composed of a pair of wheels below each motor compartment and a fifth wheel at the nose of the fuselage



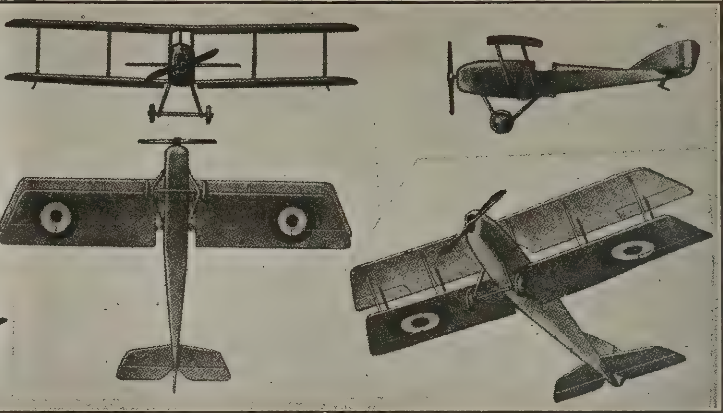
Aviatik (Aviatik-u. Automobil-Gesellschaft) (German). A fixed Mercédès 175 H.P. engine is installed. The familiar exhaust stock carries the gases from the engine and leads them over the top plane



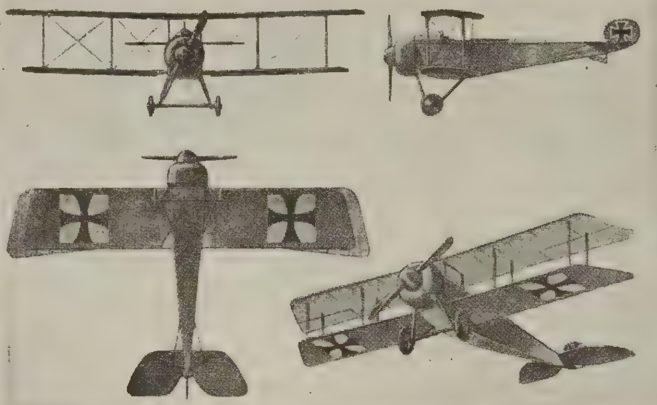
Albatros C.III. A German "all purposes" machine which carries a fixed and movable gun. Radiator carried in the upper plane. Exhaust pipes similar to that of the Aviatik



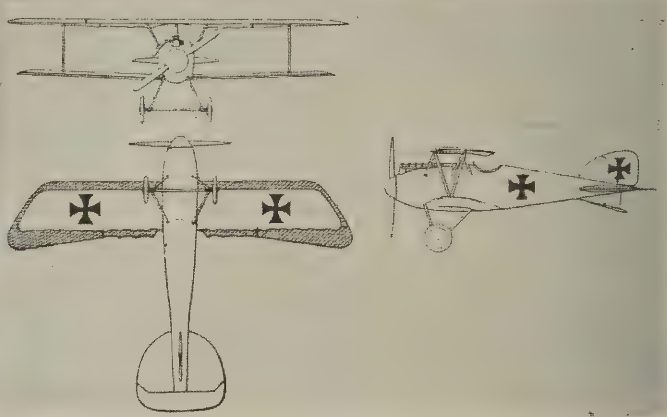
Morane-Saulnier. Employed by the British. A rotary Rhone engine is used, preceded by a streamline noseplate. The undercarriage structure resembles the letter M (initial of "Morane"). There is no fixed tail plane. The elevators are of the balanced type. Sometimes mistaken for the Fokker or Halberstadt, which are imitations of it



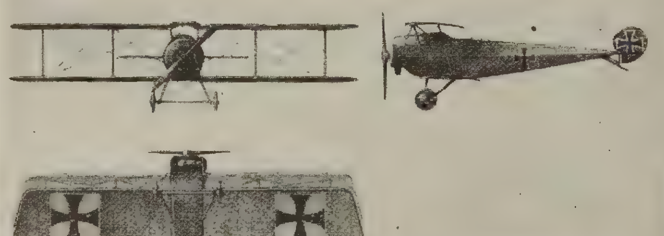
Martinside (British). Engine is a fixed Beardmore. Ailerons on upper and lower planes which are about equal in span. The tail plane is narrow in comparison with its span



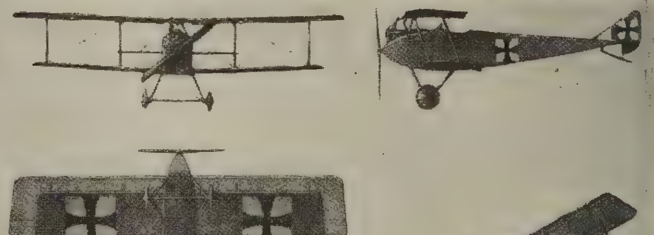
AGO (Aktien Gesellschaft Otto). A German single-seater. Rotary Oberursel engine with propeller spinner or nose-piece. The vertical rudder is balanced much in the manner of the French Nieuport. The upper plane is but slightly greater in span than the lower and both planes have practically the same chord, whereas the Nieuport has a narrow lower plane



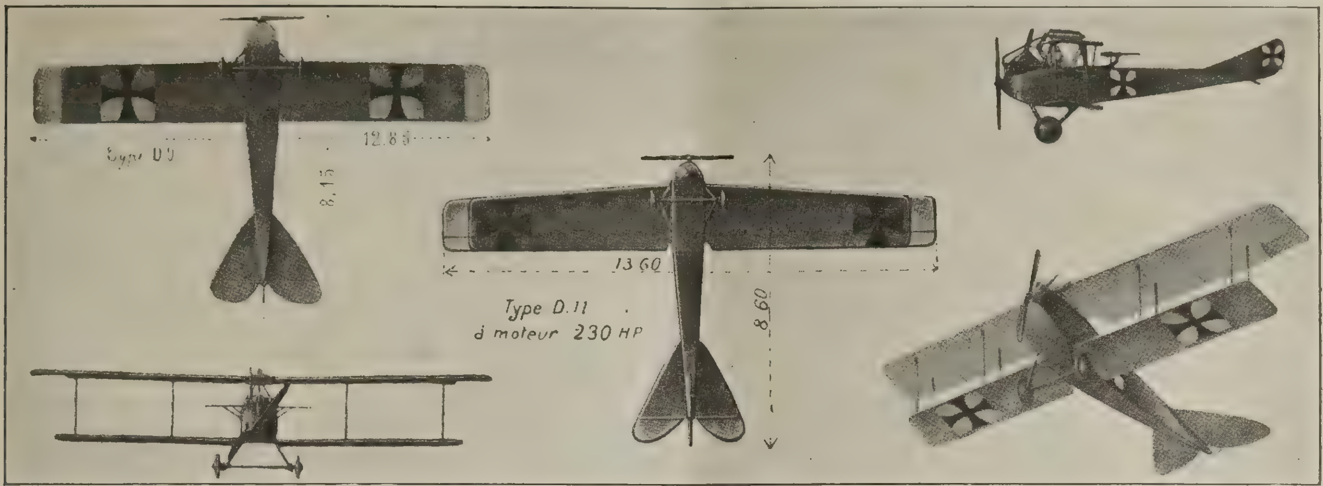
Albatros D.III (German). Single seater scout equipped with a vertical Mercedes engine. Very apt to be mistaken for a Nieuport, as it has V struts and a narrow lower plane. It has, however, a high vertical fin and an under-fin tail skid. This machine is one of Germany's fastest scout aeroplanes, the type used by the famous "Flying Circus" which for a time had things their own way in the sector at which they were stationed. Their best maneouver is the dive, which is easily accomplished because of its great weight. When it comes to climbing, the Albatros is no match for French or British machines of the same type.



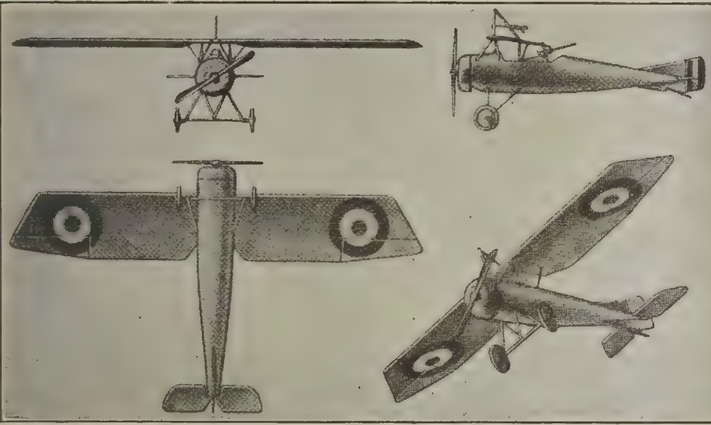
Fokker (German). Single seater scout machine, with a rotary Oberursel 100 H.P. or a fixed Mercedes 170 H.P. engine. This machine is very similar to the Morane-Saulnier, but is distinguishable by its comma-shaped balanced directional rudder and its two pairs of interplane struts. Evidently its constructors appreciate the value of adhering to Morane-Saulnier lines



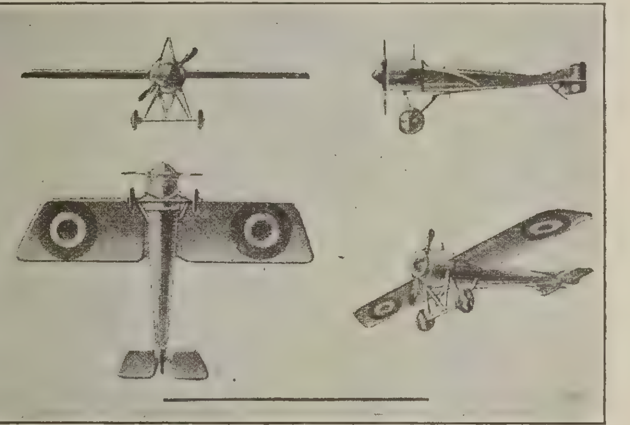
Halberstadt (German). Single seater equipped with a fixed Argus or Mercedes engine. The planes are staggered 1' 6", and the upper plane slightly overhanging, thereby differing from the Morane. Overall length, 24' 0". Span, upper plane, 28' 6"; lower plane, 25' 10". Chord, both planes, 5' 2". Gap, 4' 4". The balanced tail flaps measure 10' from tip to tip, and are 2' 4" wide



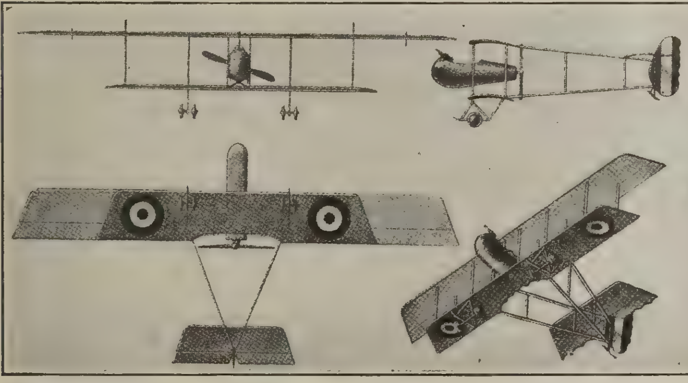
L. V. G. (Luft-Verkehrs-Gesellschaft) (German). Made in two types: Type "D9" which has a 175 H.P. Mercedes or Benz engine and Type "D11" having a 235 H.P. engine. Distinguishable by its "half-negative" ailerons and the long span of the D11, the wing chord of which is greater near the body than at the wing tips



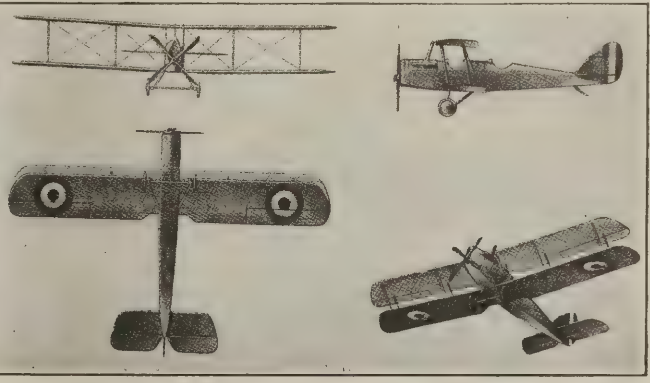
Morane-Saulnier monoplane (used by French and British). The Parasol type is equipped with a rotary Rhone engine and resembles the Morane-Saulnier biplane. Two guns are carried, one above the plane and one resting on the fuselage



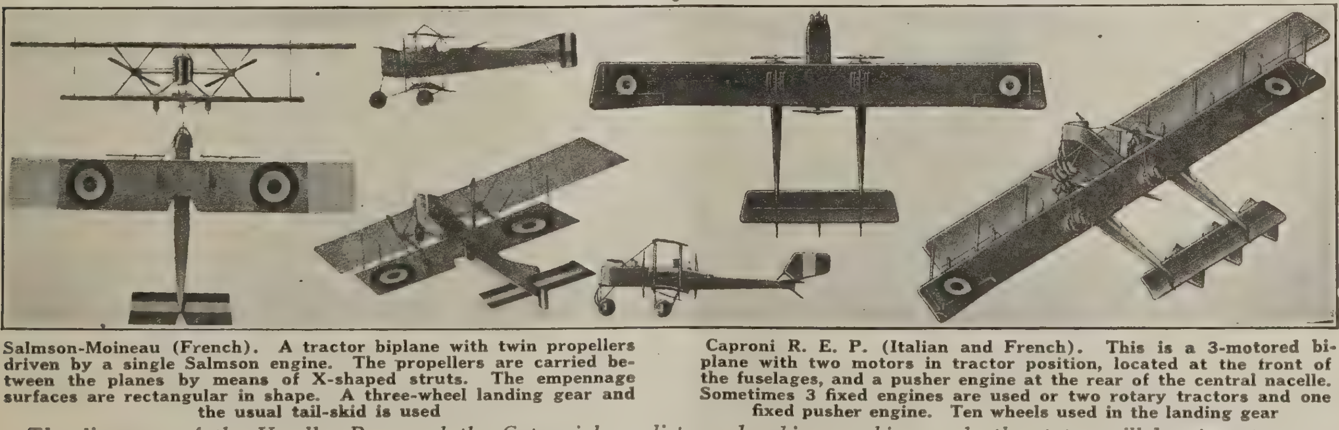
Morane-Saulnier monocoques 11 and 13 mq. In this machine the pilot's vision is above the plane. It has a very small lifting surface, and is often mistaken for the German Fokker. One of the fastest monoplanes of the present war



Farman Fréres F. 40 (French). A pusher type biplane with a fixed Renault or Lorraine-Dietrich engine. The nacelle is situated above the lower plane. Lower plane has the same chord, but about one-third less area than the upper. Ailerons on the upper plane only.



De Haviland 4 (British). Uses a V-type engine and four-bladed propeller. Planes are slightly staggered, but not swept back and very slight dihedral. Two pairs of struts used at either side of the fuselage. A balanced type rudder used



Salmson-Moineau (French). A tractor biplane with twin propellers driven by a single Salmson engine. The propellers are carried between the planes by means of X-shaped struts. The empennage surfaces are rectangular in shape. A three-wheel landing gear and the usual tail-skid is used

Caproni R. E. P. (Italian and French). This is a 3-motored biplane with two motors in tractor position, located at the front of the fuselages, and a pusher engine at the rear of the central nacelle. Sometimes 3 fixed engines are used or two rotary tractors and one fixed pusher engine. Ten wheels used in the landing gear

The diagrams of the Handley-Page and the Caproni long distance bombing machines and other types will be given in the next number of Aerial Age.

STANDARDIZED SPECIFICATIONS FOR LUBRICATING OILS

By C. W. STRATFORD, President Dixie Chemical Corporation

IN all industries the tendency toward standardization has never been stronger than at present. Under stress of war, international standardization committees are now the order of the day. The work done by these committees has been fruitful in securing the highest degree of quality, suitability and manufacturing efficiency. The oil industry appears to be one of the few remaining in which no effective standardization has been brought about. It is generally recognized that there is real need for some dependable method or methods of distinguishing between good and poor lubricating oils.

The advent of internal-combustion engines has introduced a new and important element in the lubrication of machinery, namely, much higher operating temperatures. Oils in these engines not only are exposed to high temperatures, but also are brought into intimate contact with carbureted air and products of partial or complete combustion, which contaminate them.

When the science of internal combustion-engine design was in its early stages little attention could be spared for the proper study of explosion-engine lubricants. As this type of engine approached perfection a difference in lubricating oils was soon perceived in service. Engine manufacturers soon found that certain oils gave good results while others were unsatisfactory. As their chief task, however, has been to produce engines, and not oils, their attention has been concentrated exclusively within their own field. In rare instances some engine manufacturers have made exhaustive experiments with lubricating oils, assuming that such oils bought in lithographed tins would always be of uniform quality if called by the same trade name. This assumption, erroneous on their part, has resulted in the complete nullification of much good that might have been derived from such engine tests. Unfortunately, intelligent tests cannot be made on lubricating oils in heat engines unless they are planned and carried out by operators who thoroughly understand all the features of internal combustion engine operation, as well as the fundamentals of hydrocarbon chemistry and the important secrets of the oil-refining industry. Lubricating efficiency and oil quality are distinctly a chemical matter, hence any specification seeking to limit quality and to definitely fix suitability and uniformity must repose upon a strictly chemical or physico-chemical basis.

There are so many variables in the operation of internal-combustion engines that unless all tests are run under carefully studied and uniformly limited conditions no comparison can be made with the results obtained from the lubricants in practical use. Because of the difficulty and of the great expense attached to the execution of such tests it is obvious that they should be supplanted by some laboratory methods which would make possible the determination of the same qualities and defects that are brought into unmistakable evidence in properly run engine tests or in actual service.

One of the first attempts to establish such laboratory tests was made by trying to apply the heat and the emulsion tests in the determination of the practical service value of lubricating oils. Oils that permanently emulsify with distilled water were found to rapidly decompose when used in an engine. Hydrocarbon oils showing a poor emulsion test also always suffer an undesirable decomposition when exposed to heat. Increased familiarity with these two tests soon proved to oil refiners that the best public demand was for engine oils that showed up most favorably under such tests. But the indications of these two tests were proved to be too limited to serve as a basis for judging all oils. When no "sulpho" compounds or highly unstable hydrocarbon compounds were present, the results obtained were negative. Consequently, other tests had to be evolved that would indisputably and definitely prescribe the stability (meaning resistance to chemical change) and and the suitability (correct volatility for the operating conditions) of all oils for use in internal-combustion engines.

In the light of the most recent study and exhaustive experimentation, the oxidation test appears to be the only dependable and satisfactory method by which the stability of oils can be predicted when they are used in service. The main facts shown by this test are the evaporation loss and the rate at which solid hydrocarbons are formed by polymerization or precipitation when oils are exposed to working conditions of an engine.

The distillation of finished oils under a high vacuum offers an unfailing means of determining their constituents; that is, of what groups of hydrocarbons, highly volatile or less volatile, the finished oils may consist. This test is a useful supplement to the oxidation test.

In the oxidation test oils are exposed to a uniform high temperature and the surface of the oil under test is swept by a continuous current of air, thus duplicating actual conditions to be met with in an engine.

Fractionation under conditions of high vacuum is an excellent method of making an approximate analysis of finished lubricating oils, since it permits of separating the volatile from the less volatile portions in graduated fractions. When oils show high evaporation loss the oxidation test alone cannot explain the reason for this loss. Evaporation may occur because of natural volatility or because of the occurrence of "cracking"—that is, decomposition of the oil into light portions and heavy liquid or solid hydrocarbon residuals.

CUSTOMARY ROUTINE TESTS

Before giving an extended description of the apparatus and the method of making the test it is, perhaps, well to discuss certain routine physical tests that have become traditional to the oil industry and to the oil consumer.

The problem of differentiation between groups of hydrocarbons sold under trade names is a different matter when viewed from the angle of the oil refiner, as compared to that of the final consumer. The oil refiner must have some practical tests that suffice for his purpose, but that during the processing of his distillates may enable him to produce oils having uniform properties.

A perfect knowledge of his crude oil, as well as a familiarity with all of the distillates from that crude oil, automatically build up for the refiner a series of standards which, though significant to him, are meaningless to the consumer. In most instances these standards are of little value to other oil refiners who are handling crudes of different characteristics. The meaning of these customary routine tests—gravity, flash, fire, viscosity, cold test and color—may be taken as examples. By these tests oil refiners accustomed to handling some specific crude or mixtures of crudes soon become so familiar with their distillates as to be able to condemn or approve any distillate in any stage of refining.

Gravity Test.—The first separation of crude oil into its distillates is usually controlled by their gravity. This test also indicates to the oil refiner the geographical source of the crude oil. Formerly, all oil refiners judged the quality of the light volatile products, such as fuels for engines, by gravity alone. Present-day developments, however, have shown that this is not a proper indication of volatile fuel characteristics. Gravity, as applied to any petroleum product, is of no practical significance to the consumer.

....

The flash test is used by oil refiners as a measure of volatility. The very lightest products, such as gasoline, are not controlled by a flash determination. The flash point of all other distillates and residues is generally used as an indication for necessary separation of distillates into their required fractions. The flash test made on products not contaminated is an indication of the same property as shown by the fire test. When the products are contaminated the fire test shows more nearly the real constituents of the oil examined.

Cross Section of Oxidation Oven

Neither flash nor fire tests are of major importance to the consumer because the real volatility of oils, as determined by distillation under high vacuum, gives him a true measure of oil economy in service.

Cold Test.—The cold test is usually applied only to lubricating oil fractions, and is employed by the refiner to control the finishing of his products. It is of importance to the consumer in determining the suitability of oils for use under certain climatic conditions.

Viscosity Test.—The viscosity of his products is of concern to the oil refiner only in so far as it may be required to meet the demands of the consumer. Through practical experience the consumer has learned what the correct viscosities of lubricants should be for different types of machinery.

Color Test.—As the petroleum industry developed, certain products were gradually accepted as standard because of their most obvious characteristic, color. It has long been customary to include the color value of an oil as a necessary marketing requisite, along with its other properties. The refiner takes the color of oils into consideration as being a valuable indication of their uniformity, it being also a check on correct processing. Although in the past color was was considered as an indication of purity, it has been demonstrated beyond any doubt that it alone means nothing in service to the ultimate user.

The unusually rapid development of aviation engines, and their importance for war purposes, have been the direct causes for further investigation and the carrying out of intensive study of the relative qualities of all available lubricating oils in the American market, special and otherwise, intended for use in automobile, truck and aircraft engines. In continuing this study, naturally, due consideration was given to routine oil testing as now made by oil refiners. Of these tests, gravity, flash, fire and color were soon eliminated as being non-essential, because they gave no decisive indication of the decomposition of an oil when exposed to heat. The viscosity, cold test, volatility, susceptibility to oxidation, and emulsifying properties were substituted as being the only tests actualy required. These five tests have been found to prescribe completely and accurately the stability and suitability of lubricants for the above-mentioned engines.

Recommended Lubricating Oil Specifications

The following specifications, which are recommended by the author for lubricating oils to be used in internal-combustion engines, are based on the five tests determined to be essential. In order to put them into force it would be absolutely necessary to standardize the apparatus used in the determination of all the properties indicated. This also applies to the standardization of petroleum ether. Given below are a description of this apparatus and the specifications of the petroleum ether, both of which are recommended for standardization.

The nomenclature used for designating the specifications is as follows: Aircraft engine oils, A. E. O.; automobile and truck engine oils, A. T. O.; and Knight sleeve-valve engine oils, K. S. V. O. The air-cooled motorcycle engine oils are not given a separate designation, since the oils specified for other duty can be used.

AIRCRAFT ENGINES

A. E. O. No. 1 (High Altitude or Low Altitude Winter)

1. Viscosity at 212 deg. fahr., seconds............58 to 70; desired 65
2. Cold test..................................Maximum 40 deg. fahr.
3. Boiling-point range........Maximum 4 per cent under 300 deg. cent.
4. Oxidation.......................Insolubles, maximum 0.20 per cent
   Evaporated loss, maximum 40 per cent
5. Emulsion ....Maximum trace

A. E. O. No. 2 (Low Altitude Summer)

1. Viscosity at 212 deg. fahr., seconds............80 to 90; desired 85
2. Cold test..................................Maximum 45 deg. fahr.
3. Boiling-point range........Maximum 4 per cent under 300 deg. cent.
4. Oxidation.......................Insolubles, maximum 0.20 per cent
   Evaporation loss, maximum 40 per cent
5. Emulsion ....Maximum trace

AUTOMOBILE AND TRUCK ENGINES

A. T. O. No. 1 (Summer)

1. Viscosity at 212 deg. fahr., seconds............52 to 60; desired 55
2. Cold test..................................Maximum 35 deg. fahr.
3. Boiling-point range.......Maximum 30 per cent under 300 deg. cent.
4. Oxidation.......................Insolubles, maximum 0.30 per cent
   Evaporation loss, maximum 40 per cent
5. Emulsion ....Maximum trace

A. T. O. No. 2 (Winter)

1. Viscosity at 212 deg. fahr., seconds............45 to 50; desired 48
2. Cold test..................................Maximum 30 deg. fahr.
3. Boiling-point range........Maximum 30 per cent under 300 deg. cent
4. Oxidation.......................Insolubles, maximum 0.30 per cent
   Evaporation loss, maximum 50 per cent
5. Emulsion ....Maximum trace

KNIGHT SLEEVE-VALVE OIL

K. S. V. O. (Summer)

1. Viscosity at 212 deg. fahr., seconds.........100 to 120; desired 115
2. Cold test..................................Maximum 52 deg. fahr.
3. Boiling-point range........Maximum 3 per cent under 300 deg. cent.
4. Oxidation.......................Insolubles, maximum 0.20 per cent
   Evaporation loss, maximum 30 per cent
5. Emulsion ....Maximum trace

Winter, use A. E. O. No. 2

AIR-COOLED MOTORCYCLE ENGINES

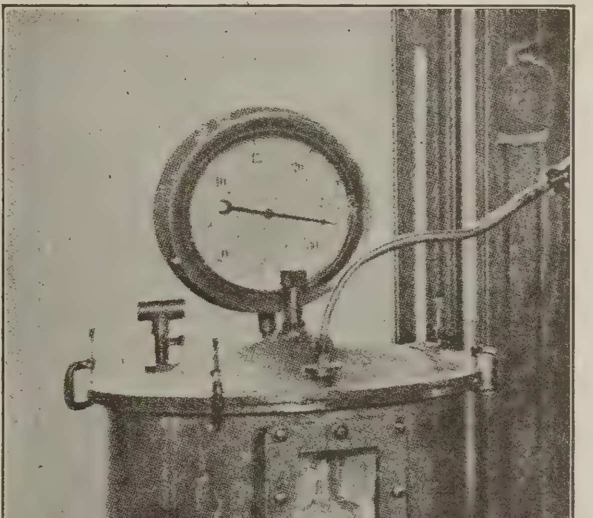
Winter—One- and two-cylinder types, use A. E. O. No. 2.
Four-cylinder types, use A. T. O. No. 1.
Summer—One- and two-cylinder types, use K. S. V. O.
Four-cylinder types, use A. E. O. No. 2.

I. Viscosity

It will be necessary to determine only the viscosity at 212 deg. fahr. For the purpose of a more thorough investigation the rate of fall of viscosity between low and high temperatures, three points may be found: 100, 150 and 212 deg. fahr.

Care should be exercised in maintaining the temperature of the oil being run at 212 deg. fahr.

The instrument used will be a standard Saybolt universal viscosimeter. Limit of error plus or minus one second.



Receiver for distillation apparatus

II. Cold Test

The cold-test box (18 by 18 by 14 in. high) is filled about three-quarters full with ice and salt mixture (about 10 to 1 by volume). Copper cylinders 9 in. high, and having an inside diameter of 2 in., are inserted in this mixture so that the tops of the cylinders are about level with the surface of the ice and salt mixture. Regular 4-oz. oil sample bottles and approximately 5-in. immersion, cold-test thermometers, having a range of from 20 to 140 deg. fahr., complete the equipment. The procedure of test is as follows:

A sample bottle is filled about one-third full of oil, and a cork, carrying the thermometer, inserted in the neck of the bottle so that the bulb of the thermometer is immersed in the oil. The sample is then placed in one of the copper cylinders. The bottle should not be allowed to come in contact with the bottom of the tube, a thin section of cork being interposed between the two. The temperature of the oil, as shown by the thermometer, is carefully observed, and at each drop of 2½ deg. fahr. the sample is removed and examined. The temperature at which the oil just refuses to flow when the bottle is held in a horizontal position is taken as the cold test.

The above method is for oils having a cold test under 40 deg. fahr. Those having cold tests above this point are tested as follows:

The point at which the oil just refuses to flow is obtained in exactly the same manner as described above, and the oil is then chilled 20 deg. fahr. below this point. The sample is then removed and placed in water which is kept just 5 deg. warmer than the oil, as shown by the thermometer in the bottle. The sample is tested at each 2½ deg. fahr. increase in temperature, and the temperature at which the oil will flow evenly across the bottle when it is held in a horizontal position is called the cold test.

The limit of error is plus or minus 2 deg. fahr.

Annapolis Pour Test.—The procedure is exactly the same as that given above for oils under 40 deg. fahr. cold test, except that 5 deg. fahr. is added to the point observed as cold test and is reported as pour test.

The above method is used for all oils except black oils. The cold test for black oils is taken at the Annapolis Experimental Station as follows: The oil is chilled by exactly the same procedure as above; when the oil just refuses to flow the sample is removed, the bottle held horizontally and the oil stirred with the thermometer. The temperature when the oil flows freely is recorded as the pour test.

A. S. T. M. Pour Test.—The method specified by the A. S. T. M. is exactly the same as that used at the Annapolis Station, except that the sample shall be removed and tested for every 5 deg. drop in temperature, instead of 2½ deg. fahr., as used at Annapolis. The difference between the A. S. T. M. and Annapolis methods is about 2 deg., and generally the Annapolis method will give the higher test.

III. Boiling-Point Range (Vacuum Distillation)

The apparatus for making this test consists of a special steel still and vapor tower, a special water-cooled condenser and chamber for the distillate receivers. The position of these receivers can be adjusted from the outside without alteration of the pressure in the distillation system. The distillation system is connected with a pump capable of maintaining a vacuum of 2½ mm. absolute and having a capacity of 6 cu. ft. per minute.

The still is charged with 2000 cc. of the oil under examination. The standard vacuum, 40 to 50 mm. absolute, is established throughout the closed system, and heat applied to the bottom of the still. For the purpose of the specification it will be necessary to carry the distillation only to the point at which the still temperature has reached 300 deg. cent. (572 deg. fahr.). The percentage of distillate up to 300 deg. cent. has been arbitrarily taken as a basis for judging the relative volatility of different lubricating oils. However, for the ultimate analysis of finished lubricating oils, the distillation may be continued up to the point where nine-tenths of the total charge will have passed over, the rest being allowed to remain in the still, and estimated as residual.

The fractionation of finished lubricating oils under high vacuum is a satisfactory way of determining boiling-point limits with the least de-

composition. The quantity of low-boiling-point fraction varies widely in lubricating oils intended for use in different types of internal-combustion engines. All engines that operate under approximately full load and at high temperatures (aviation engines) should contain a minimum quantity of low-boiling-point fractions, say 4 per cent distilling under 300 deg. cent. The results obtained by actual tests in aircraft engines clearly demonstrate this point. On the other hand, passing from such conditions of high operating temperatures to those of widely varying and comparatively low operating temperatures (passenger cars and trucks), it is necessary to increase materially the quantity of low-boiling-point fractions to prevent serious carbonization. There is a limit, however, to the addition of low-boiling-point fractions, for the reason that too large a quantity will greatly increase the specific consumption of the lubricant in service, hence some mean value must be fixed upon, a permissible balance being struck between carbonization and high consumption. An analysis of the most successful automobile oils now sold shows that not over 30 per cent of the oil should distill below 300 deg. cent. in the vacuum distillation apparatus described. This volatility is a guarantee of a reasonably low specific consumption, good lubrication and minimum carbonization within the explosion chambers.

Oxidation Test

The apparatus for making the oxidation test consists of a cubical box constructed of heat-insulating material. Through the vertical axis of this box passes a shaft, at the center of which is attached a disk of about 11 in. diameter. This disk and shaft are rotated at a speed of 25 r.p.m. The containers for oil samples are steel cups cut from the solid, 50 mm. inside diameter, plus or minus 0.04 mm.; and 50 mm. high, plus or minus 0.4 mm. The cup wall is 1 mm. thick. The oven is electrically heated by resistance coils, and the temperature is maintained constant and regulated by a thermostat. Air circulation is provided through holes in the bottom of the sides of the oven and through the top. The determinations made in this oven are:

1. Evaporation loss.
2. Petroleum ether insolubles.
3. "Varnish."

Fifty grams of the oil are weighed into the cups, and these are placed at equal distances at the outer edge of the rotary disk. The temperature is brought to 225 deg. cent., and the test is continued at this uniform temperature for twelve hours, in two periods of six hours. The samples are then removed and allowed to cool, weighed, and the loss in weight (per cent) recorded as evaporation loss. The contents of the cups are then washed through a Gooch crucible with standardized petroleum ether (see below) until the filtrate is colorless. From the crucibles on which remain the insoluble residue the petroleum ether is allowed to evaporate, after which they are introduced into a Freas oven and thoroughly dried at a temperature of 105 deg. cent. The weight of the residue is then determined and the percentage recorded as petroleum ether insolubles.

When the metal cups have been thoroughly washed with petroleum other there still remains a varnish-like residue, which clings to the upper walls. The weight of this substance is determined and recorded as "varnish."

The real significance of "varnish" values has not been clearly established up to the present. Poorly refined oils, however, also those from some mid-continent and from California crudes, usually show high "varnish" values.

The maximum variation of checked results on evaporation loss and petroleum ether insolubles should not exceed 2 per cent.

It has been found that the evaporation loss of an oil does not always coincide with its boiling-point range; therefore, it seems permissible to conclude that the evaporation loss is a measure of the decomposition of an oil, as well as of its volatility. In judging oils it is important to observe carefully the relation between the boiling-point range and the evaporation loss. For example, an oil may have a high boiling-point range, and yet, owing to its instability, may readily decompose when exposed to heat, and thus show a high evaporation loss.

The petroleum ether insolubles indicate, on the one hand, the solid carbonaceous matter formed in an oil, which splits up, when exposed to heat, into light volatile ends and solid products. On the other hand, these insolubles may indicate the precipitation of colloidal carbon or other products in improperly refined oils. Values of petroleum ether insolubles may be entirely independent of those of boiling-point range or evaporattion loss.

Standardized Petroleum Ether

For the determinations of petroleum ether insolubles it is imperative that a standardized petroleum ether be employed, such as the following:

Petroleum ether should be made from steam-stilled Prime City naphtha from Pennsylvania crude, which has the following proporties:

Gravity, deg. Baumé, 72 to 76.
Initial boiling point, deg. fahr., 110 to 122.
Final boiling point, deg. fahr., not over 270.

Petroleum ether should conform to the following specifications:

Gravity, deg. Baumé, 77 to 80 (the matter of gravity is unimportant).
Initial boiling point, deg. fahr., 110 to 120.
Final boiling point, deg. fahr., 220 to 245.
Unsaturated content not over 4 per cent by absorption in sulphuric acid (Bureau of Mines method).

The Saybolt distillation method applies to both of the above boiling-point ranges.

V. Emulsion Tests

In making emulsion tests the simple apparatus described below gives excellent check results.

The apparatus consists of a Coles milk shaker slightly altered to receive two 4-oz. oil sample bottles. The shaker is operated at a speed of 600 r.p.m., and has a 2-in. stroke.

About 1½ in. of oil and an equal quantity of distilled water is poured into the bottles, which are then corked and placed in the machine. These are shaken for half an hour, after which they are removed and allowed to stand at room temperature for 24 hours. The amount of unseparated oil is then determined and recorded as emulsion.

The above method applies only to oils having a viscosity not exceeding 50 sec. at 212 deg. fahr. When the viscosity exceeds this figure the oil should be blended with 50 per cent of standardized petroleum ether before shaking.

For the purpose of the specification the emulsion value of an oil can be considered as a quantitative test for "sulpho" compounds.

Author's Conclusion

These investigations were suggested by H. L. Horning, chairman of the Automotive Products Section, War Industries Board, Council of National Defense, who requested the author to make a thorough study of hydrocarbon lubricants for aircraft engines in the search for the best oil. The specifications as drawn above represent the results of these studies, which were begun in June, 1917, and terminated early last December.

In securing the data on which these specifications are based valuable assistance was received from a number of sources. The Tidewater Oil Company, Bayonne, N. J., permitted the author the use of its extensive laboratories for a number of months with the full collaboration of S. E. Campbell, chief chemist.

Credit should also be given Dr. C. E. Waters of the Bureau of Standards for information furnished regarding his oxidation oven and tests.

Dr. E. W. Dean of the Bureau of Mines made valuable suggestions relative to the distillation of hydrocarbons under high vacuum.

AEROPLANE'S PARTS AT A GLANCE

THE long felt need for a simplified table to show at a glance the different parts of an aeroplane and give their technical nomenclature has been supplied by the issue of a pamphlet by the Aviation Department of the William Hood Dunwoody Industrial Institute.

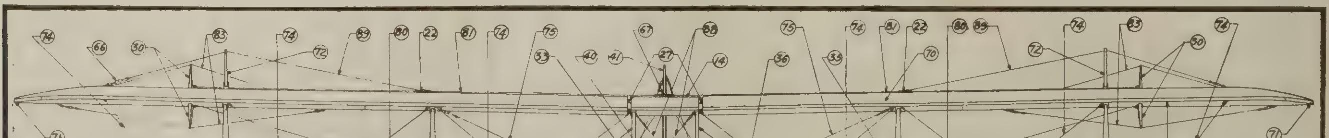
This pamphlet was prepared under the direction of Captain E. W. Farrow, formerly of the British Royal Flying Corps, who is in charge of the Aviation Department

It is an example of the thoroughness in which the patriotic members of the Aero Club of Minneapolis—which is responsible for the establishing of the Aviation Department at the Dunwoody Institute—does things.

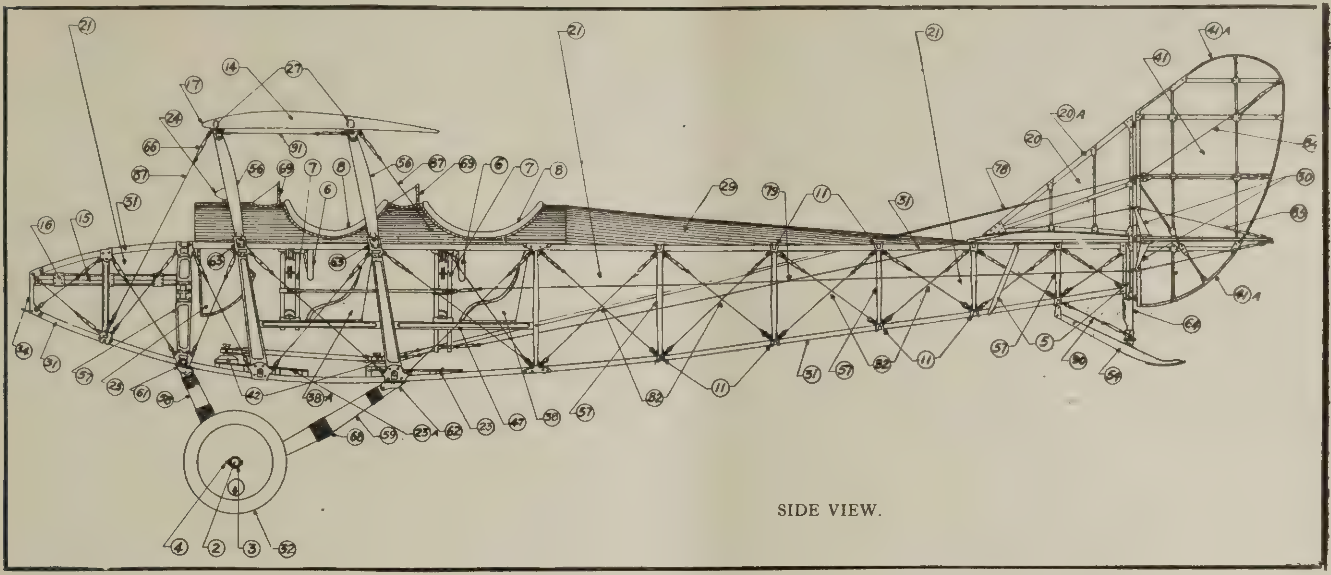
Every aviation student wants such information, and will be thankful to the Aero Club of Minneapolis, the Dunwoody Institute and Captain Farrow for it.

The nomenclature accompanying the diagrams follows:

T. 1. Aileron—A small wing usually situated at the outward end of the trailing edge, the operation of which turns an aeroplane about its longitudinal axis; causes an aeroplane to tilt sideways.
S. 2. Axle—Welded steel tubing with reinforced wood filler.
S. 3. Axle Collar—Machined brass, used to prevent wheels from coming off.
S. 4. Axle Collar Bolt—Hexagon head, passes through axle collar and axle, and is secured by castellated nut.
S.F. 5. Braces—Horizontal, stabilizer, steel tubing streamlined with spruce form, and covered with linen tape and dope.
S. 6. Control Wheel—Two in one, controls ailerons and elevators.
S. 7. Control Yoke—Non-magnetic aluminum tubing, fastened to seat rails by two trunions and bearings, and to which control wheels is secured.
S.T. 8. Cockpit—Pilot's, padded.
T. 9. Cowl—Top engine, sheet aluminum secured to side cowling by two straps and buckles.
F. 10. Cowl—Bottom, sheet aluminum.
F. 11. Clips—Fuselage, hold compression struts, fuselage diagonal bracing wires are also attaached.
T. 12. Distance Piece—A long, round piece of spruce running full length of wing and used to prevent ribs from rolling over.
T. 13. Elevator—A controlling surface usually hinged to the rear of the tail-plane the operation of which directs an aeroplane upwards or downwards.
S.T.F. 14. Engine Section Panel—Upper wings are attached to engine section panel.
S. 15. Engine Bed—Four laminations, two center spruce, outside hardwood, are used as engine supports.
S. 16. Engine Bed Protector—One thirty-second inch sheet steel wrapped around bed to prevent engine from sinking into wood.
S.T. 17. Edge Leading—The front edge of a surface relative to its normal direction of motion.
T. 17a. Edge Leading Form—Spruce.
T. 18. Edge Trailing—The rear edge of a surface relative to its normal direction of motion.
T. 18a. Edge Trailing Form—Flattened steel tubing.
T. 19. Fabric—Irish linen, shrunk and tightened by applying about six coats of dope and two of varnish.
T.S. 20. Fin, Vertical—A fixed vertical surface, used as a keel, and to prevent the machine from tail-spinning.
S. 20a. Fin, Vertical Form—Flattened steel tubing.
S.T. 21. Fuselage—The body of the aeroplane holding the motor, fuel, pilot, and passenger, and to which is fastened the panels and tail unit.
T. 22. Fair Lead—Used to prevent sway of control wires.
S. 23. Floor Board—Pilots, made of hard wood, used to attach rudder bar to.
S. 23a. Floor Board—Passenger.
S. 24. Gasoline Sight Gauge—Showing quantity of fuel in tank.
S. 25. Gasoline Tank—Heavy gauge tin.
F. 26. Gap—The distance between the upper and lower wings of a biplane.
F.S.T. 27. Hinges, Wing—Female on panels, male on engine section and connected by wing hinge pin.
T. 28. Hinges, Aileron—Male and female, used to connect aileron to panel by a hinge pin.
T.S. 29. Inspection Cover—An accessible streamline cover, fastened to upper longerons by four hinges on each side, can easily be removed to inspect control wires and fuselage bracing wires.
S.F. 30. King Posts or Control Posts—Used on controlling surfaces as a lever for control wires.
S. 31. Longeron—Generally white ash, running the full length of the fuselage and around which all the body of the machine is built up.
S.F. 32. Landing Wheels—Tangent wire wheel, pneumatic tires, spokes and rim covered by doped fabric to streamline wheels.
F.T. 33. Motor—Power-plant used to propel aeroplane.
S. 34. Nose-Plate—Shaped sheet steel, used to connect four longerons and holds radiator in place.
F. 35. Pitot-tube Head—The air passes through head and metal tubing to indicator which measures the velocity of an aircraft with reference to the air through which it is moving, usually calibrated in miles per hour.
F.T. 36. Propeller—Oak, mahogany, or walnut, five laminations so shaped that its rotation about an axis produces a force (thrust) in the direction of its axis. Includes both pusher and a tractor prop.
Panel or Plane—See wing.
F. 37. Propeller Hub—Machined steel, connects prop to crank shaft.
S.T. 38. Pilot's Seat—Upholstered bucket seat.
S. 38a. Passenger's Seat—Upholstered bucket seat.
T. 39. Pulley—Aileron compensating wire, ball-bearing pulley through which wire passes without friction.
F.T. 40. Radiator—Contains four and one-half gallons of water, used to cool motor.
S.F.T. 41. Rudder—A hinged or pivoted surface attached to the rear of tractor machine. Used to steer a course or direction.
S. 41a. Rudder Frame—Flattened steel tubing.
S. 42. Rudder Bar—Pilot's and passenger's, is dual control, ash bar, copper tipped, mounted in center on a swivel and each end connected to a control cable running to rudder.
T. 43. Rib, Compression—Acts as a lightened rib, besides bearing the stress of compression produced by the tension of internal bracing wires.
T. 44. Rib, Lightened—A curved wooden part assembled in a panel and used to give the panel its curvature and convey the lift from the fabric to the spare.
T. 45. Rib Nose—Same purpose as forty-four, but runs from leading edge form to front of main spar only.
T. 46. Rib, Nose Form—Three-ply wood, a curved form on top of forty-four, its purposes being to take fabric and keep it to its proper curvature and prevent its sagging.
S. 47. Seat Rail—Spruce I-beam running from station behind pilot's seat to station in front of passenger's seat, supports pilot's and passenger's seats, also see No. 7.
T. 48. Spar, Main—Spruce I-beam within a panel and to which all ribs, drift and anti-drift wires are attached.
T. 49. Spar, Rear—Same as forty-eight except situated in rear portion of panel.
T. 50. Spar, Tail Plane Main—Same purposes as forty-eight.
T. 51. Spar, Tail Plane Rear—For same purposes as fifty but of lighter construction, elevator is attached to it by hinges.
F. 52. Shock Absorber, Landing Gear—Two pieces of rubber ten feet long absorbs and minimizes the shock of a landing.
53. Shock Absorber, Tail Skid—Rubber, same as fifty-two, only situated at rear of machine.
S. 54. Skid, Tail—Made of white ash or other hardwood. Carries weight of rear portion of machine while on the ground, also acts as brake in landing.
F. 54a. Skid, Wings—Made of rattan. Protects and keeps wing tips from ground in case of bad landing.
F. 55. Struts, Wing—Made of spruce because it has a high compression strain for its weight. Used to keep upper and lower planes apart.
S.F. 56. Strut, Engine Section—Spruce, holds engine section panel to which upper planes are attached.
S. 57. Strut, Fuselage—Spruce, acts as spacer and keeps the four fuselage longerons apart.
S.F. 58. Strut, Landing Gear, Front—Spruce, reinforced by binding with linen twine.
S. 59. Strut, Landing Gear, Rear—Same as fifty-eight.
F. 60. Stream-Line Spacer—Used as a stream lining for axle, also acts as a spacer for wheels.
S. 61. Socket, Landing Gear, Front—Made of sheet steel, used to connect landing gear strut to fuselage.
S. 62. Socket, Landing Gear, Rear—Same as sixty-one.
S. 63. Socket, Engine Section Strut—Sheet steel, holds engine section strut, fuselage strut and diagonal bracing wires.
S. 64. Tail Post—White ash laminated, sometimes spruce. Vertical post finishing the streamline effect of the fuselage, and to which the four longerons are secured. The universal joint of tail skid and two hinges of rudder are also fastened.
T. 65. Tail Plane—A horizontal stabilizing surface attached by bolts to the rear portion of fuselage and to which the elevators are attached.
F.S. 66. Turnbuckle Fork—Consists of brass and alloy of man-



FRONT VIEW.



SIDE VIEW.

ganese barrel, fork with right hand thread always attached to fixed portion of machine and an eye with left hand thread which is attached to loop of cable or wire by splice. A turnbuckle is used to tighten or adjust cables or wires.

T. 67. **Turnbuckle, Eye**—Used to connect two wires, so two eyes are used instead of one fork.

F.S. 68. **Winding, Landing Gear Strut**—Bound with linen twine to reinforce and prevent splintering.

S. 69. **Wind Screen**—Made of celluloid with aluminum frame, used to deflect wind and oil from passenger or pilot.

F.T. 70. **Wing**—The supporting surfaces of an aeroplane.

F.T. 71. **Wing Tip**—The extreme right or left hand end of a wing.

F.T. 72. **Wing Masts**—Spruce with copper banding at each end, used as a truss for cable which supports upper wing extensions when machine is on the ground.

F. 73. **Wires, Landing**—Stranded steel cable, used to take load of wings when machine is landing or on the ground, also used for adjusting dihedral angle of machine.

F. 74. **Wires, Flying**—Duplicated stranded steel cable, used to take load of machine while flying; these wires prevent wings from folding upwards when flying.

F.T. 75. **Wires, Drift**—Stranded steel cable, used to prevent wings from folding backwards when flying.

T. 76. **Wires, Anti-Drift**—Piano wire, diagonal bracing wires used to adjust wing framework and to hold rigid.

T. 77. **Wire, Drift (Wing)**—Piano wire, same purposes as seventy-six.

S.T. 78. **Wire, Rudder Control**—Flexible stranded steel cable, used to connect rudder-bar to king-posts of rudder.

S.T. 79. **Wire, Elevator Control**—Flexible stranded steel cable, used to connect control yoke to king-posts of elevators.

F. 80. **Wire, Aileron Control**—Flexible stranded steel cable, used to connect control wheel to aileron king-posts.

T.F. 81. **Wire, Aileron Compensating**—Flexible stranded steel cable, used to balance and adjust ailerons.

S. 82. **Wire, Fuselage, Diagonal Bracing**—Forward half of fuselage are duplicated stranded steel cables, rear half are piano wires.

F.T. 83. **Wire, Aileron Control Bracing**—Piano wire, used to brace king-posts, and to prevent warping of ailerons.

S.T. 84. **Wire, Rudder Control Bracing**—Piano wire, same function as eighty-three.,

F.T.S. 85. **Wire, Elevator Control Bracing**—Same function as eighty-three.

F. 86. **Wire, Landing Gear Diagonal Bracing**—Heavy stranded steel cable, used to hold landing gear rigid and to take strains in landing.

S. 87. **Wire Engine Section Bracing**—Heavy stranded steel cable used to adjust stagged on engine section.

F. 88. **Wire, Engine Section Diagonal Bracing**—Heavy stranded steel cable, used to hold engine section rigid and take strain of machine both when on the ground and flying.

F.T. 89. **Wire, Overhang**—Stranded steel cable, runs over wing mast and takes load of extension when machine is on ground.

S. 90. **Wire, Tail Post Bracing**—Piano wire, used to brace tail post and take strain from tail posts in a fast landing.

S. 91. **Wire, Engine Section Tie**—Stranded steel cable, used to connect engine section struts from spreading.

THE "CROCCO" ROUTE INDICATOR AND ITS NOTEWORTHY APPLICATIONS*

THE preponderance of the study of statics and of dynamics of aircraft has for a long time caused the study of the methods of navigation to pass into a secondary place, although these are of very great importance for all practical purposes. From the evident similarity between aerial and maritime navigation, it can easily be believed that the same methods which have reached the highest state of perfection in maritime navigation may be applied to aerial navigation; but it should be remembered that the space in which an aeroplane moves generally possesses a motion with velocity of the same intensity as the velocity of the aeroplane, and it may be understood at once that the case of navigation in the air is essentially different in this respect to that of navigation in the sea where the currents usually have a very low velocity.

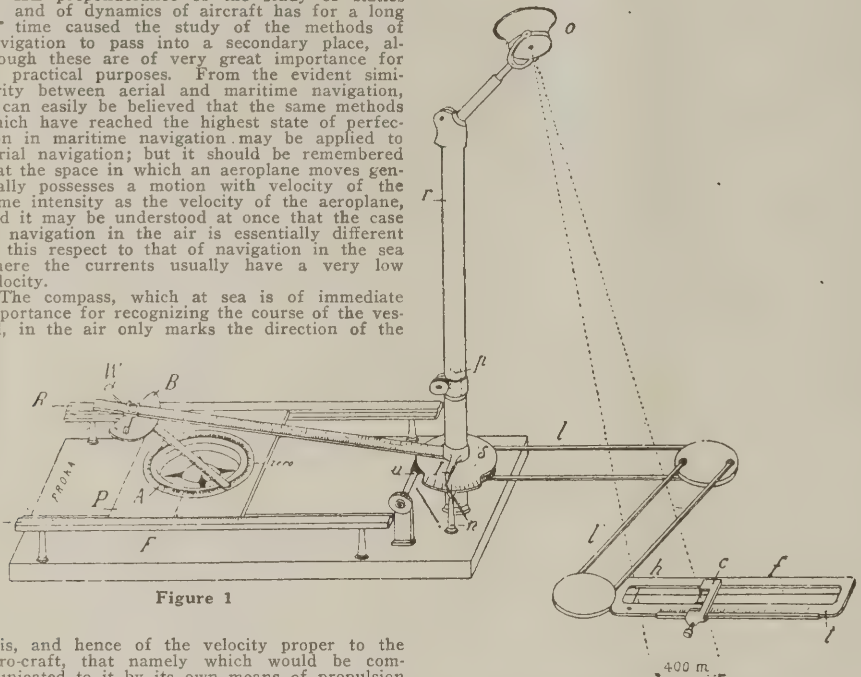

Figure 1

The compass, which at sea is of immediate importance for recognizing the course of the vessel, in the air only marks the direction of the axis, and hence of the velocity proper to the aero-craft, that namely which would be communicated to it by its own means of propulsion in completely calm air. The real velocity with regard to the ground, which is that which is of interest for navigation, as it is the resultant of the velocity of the aeroplane and of the velocity of the wind, has in general a direction very different to that which is indicated by the compass, which, therefore, by itself cannot give the pilot an exact measurement of the orientation of his course. The pilot, however, may count on the compass to guide him, if he have at his disposition a route indicator, which allows him either to pass from the indication of the compass to the real course or to deduce from the orientation of the determined route the compass indication which has to be followed by the pilot.

Notwithstanding the importance of the two above-mentioned problems, it is difficult to find among the large production of books on aeronautics an adequate note on them and a solution which would be of use rapidly in practical cases.

When I previously† considered this question I proposed a very simple instrument for the determination of the necessary elements for the correction of the route by the deviation due to the wind (drift angle, effective velocity), which at the experiments which I carried out gave sufficiently satisfactory results. For their description I refer my readers to the last of the above-mentioned notes: my aim is to examine here an instrument for route indicating invented by Lt.-Col. Crocco, which presents the possibility, in addition to solving the above-mentioned questions in every detail during the flight, of solving many other problems belonging to navigation and to gunnery, and which therefore are of the greatest interest; I will then touch upon some of its notable applications.

Fig. 1 represents diagrammatically the apparatus of which a photograph is produced herewith; we shall distinguish two parts in it: one destined for the solution of the first of the above-mentioned problems—namely, to recognize the orientation of the actual effective motion of the aeroplane, which in general, as I have already pointed out, differs from the correct indication of the compass, by a certain angle called drift angle, the other which more properly deserves the name of route indicator, destined to solve the second problem—namely, to get the indication for the use of the pilot to be able to follow a given route. In general such indication differs from the direction of the fixed route by a certain angle which is called "angle of pilotage."

The first part of the apparatus consists in a pointing instrument which allows the determination of the orientation of the apparent motion of the points of the ground over which the aeroplane is flying; this is equivalent to determining the direction of effective motion, since evidently the points of the ground seem to the person who is on the aeroplane to remain behind in the same direction along which the aeroplane really moves, and the velocity with which they seem animated is equal to the real velocity of the aeroplane.

On the pivot *ρ*, which is solidly fixed on board the aeromotor, let a coupling box *m* be fixed; this is movable round the pivot by means of a micrometric screw *u* and is furnished with a graduated sector *δ*; by this means we can measure the angle by which it is revolved with respect to a pointer *n* fixed at the base of the apparatus. Two pivots are fixed on to this coupling box round which the two equal sides of the articulated parallelogram *l* turn, which, by means of a second articulated parallelogram *ν* sustains the aim or sight-vane *t*.

This consists of a rectangular plate, crossed in its greatest length by a groove through the middle of which a wire *f* is stretched. Along the sight-vane a slider *c* is movable, and on the edge of the sight-vane a graduation is engraved calculated in such a way that it allows, when the height of the aeroplane is known, by limiting a length of wire between the slider and the fixed extremity *h* that when seen through the sight *o* it covers over the ground a length of 400 meters; and this is done by simply bringing the slider on to the level of the graduation marked with the aforesaid height.

The screw *u* allows any orientation whatever to the wire itself, and it is clear that when the screw is fixed the articulated parallelograms allow the sight-vane to be moved in its own place, so that the wire always remains equally oriented. The apparatus is mounted on board in such a

†M. Tenani, "Instruments and Methods of Aerial Navigation," in *Rivista Italiana d'Aeronautica*, Rome, February, 1917, and the notes of A. lithographed by the Government Aerological Station P. of Vigna di Valle, entitled "Measurements of the Velocity of the Wind and of the Pilotage Angle during Flight, and on the Correction of the Route from Deviation due to the Wind" (March, 1917).

way that when the zero of the graduation of the sector δ opposite the fixed pointer *n*, the wire becomes parallel to the axis of the aeroplane—namely, to the direction of the velocity proper of the aeroplane. Now let us choose any point whatever on the ground and let us move the sight-vane in such a way that looking from *o* the point *h* may be found in correspondence with the observed point.

If as time passes the point observed seems to slide along the wire of the sight-vane, that will mean that the wire will have the direction of the motion of the points on the ground; that is, according to what has been said above, it will have the orientation of the effective motion. If this does not happen, by turning the micrometric screw it will be easy to give suitable orientation to the sight-vane, and after a few experiments, when the sight-vane is well adjusted in the aforesaid way, we shall be able to read on the sector δ, through what angle it should be turned, with regard to its zero position—namely, by how many degrees the orientation of the real motion differs from the orientation of the proper motion of the aeroplane (drift angle). For this reason the sector δ is called the *drift sector*.

Let us count by means of a chronometer how many seconds pass between the moment in which a point on the ground is in correspondence with the fixed point *h* and the moment in which it is seen in correspondence with the slider; this will be the time taken from the point in its apparent motion, or of the aeroplane in its real motion to travel 400 meters. Hence the effective velocity is at once deduced in meters per second at which the aeroplane moves with respect to the ground, dividing 400 meters by the number of seconds employed for taking the measures, but, as we shall see, it is not even necessary to make this division, because on one of the sides of the apparatus, which we will describe later, we have a double scale, in seconds and in meters, which gives the result of the division facing the numbers of seconds.

As we have seen, the part of the apparatus which we have described allows us to deduce, by the proper orientation, the real orientation of the motion; and that orientation adding to or subtracting from its proper orientation (counting from the north in degrees in the direction of the hands of a watch, as is supplied by the compass when corrected for magnetic declination, and for deviation due to the iron existing on board) the drift angle, according as it is righthand (that is, the effective motion is moved to the right of the axis) or left; and allows the real velocity of the motion to be determined.

Let us note further that the apparatus presents the possibility of plotting out the passage of the points on the ground in another way—namely, by fixing the sight-vane directly to the coupling box and rendering the sight *o* movable in a horizontal plane by means of suitable articulations, supported by the pivot ρ.

Figure 2

It is easily understood how the apparatus itself may be used when it is wished to determine the direction and the velocity relative of the aeroplane, with respect to a movable point on the ground, when it may be supposed that this moves with uniform velocity and in a straight line (for instance, trains, motor-cars, ships) for artillery targets.

Let us now see how we may by means of the other parts of the instrument solve the second problem we have mentioned—namely, the finding of the compass indication, which will enable the pilot to follow effectually a fixed route. The following consideration will be useful to us. Let us draw a triangle as shown in Fig. 2, in which AB represents the proper velocity to the aeroplane in size and direction AC represents the effective velocity in size and direction; the included angle will be the drift angle (in the figure, drift on the right). The third side BC of the triangle will evidently represent the velocity and the direction of the wind which, combined with the proper velocity, gives us the resultant effective velocity. It is clear that the angle ABE (equal to its opposed angle DBC, which is the angle included between the axis of the fuselage and the direction of the wind, and which is called for this reason "head wind" angle) counted in the direction of the hands of a watch from the side AB to the side EB represents the angle through which it is necessary to turn (in the same sense) the proper direction so as to get the direction in which the wind proceeds. So that, knowing the head wind angle, it is sufficient to add it to the proper orientation indicated by the compass in order to obtain the orientation of the wind velocity.

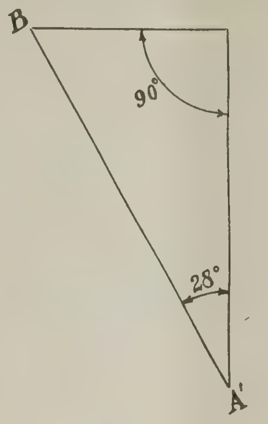

Figure 3

Let us observe in the meantime that the velocity and direction of the wind, obtained in this way, does not vary rapidly in the time (as the soundings by pilot balloons show at least at heights exceeding 500 meters from the ground); so that we may consider the direction and the velocity of the wind as constant within sufficiently ample limits of time. Let us observe then that if the route is marked on the map in degrees from the north, the pilot will be certain of passing over it when the angle always counted in the same direction, included between the effective velocity and the direction of the wind ("wind-velocity effective angle") shall be equal to the angle, which may be easily calculated, included between the fixed route and the direction of the wind ("wind-route" angle). Now the effective wind velocity angle is the angle ACB of our triangle; therefore, if this angle be different from the "wind-route" angle, and hence the fixed route is not followed, we may construct another triangle A′B′C′ which has for sides the velocity of the aeroplane on the ground and let us move the sight-vane in such a way that looking from *o* the point *h* may be found in correspondence with the observed point.

If as time passes the point observed seems to slide along the wire of the sight-vane, that will mean that the wire will have the direction of the motion of the points on the ground, that is according to what has been said above, it will have the orientation of the effective motion. If this does not happen, by turning the micrometric screw, it will be easy to give suitable orientation to the sight-vane, and after a few experiments, when the sight-vane is well adjusted in the aforesaid way, we shall be able to read on the sector δ, through what angle it should be turned, with regard to its zero position—namely, by how many degrees the orientation of the real motion differs from the orientation of the proper motion of the aeroplane (drift angle). For this reason the sector is called the *drift sector*

Let us count by means of a chronometer how many seconds pass between the moment in which a point on the ground is in correspondence with the fixed point *h* and the moment in which it is seen in correspondence with the slider; this will be the time taken from the point in its apparent motion, or of the aeroplane in its real motion to travel 400 metres. Hence the effective velocity is at once deduced in metres per second at which the aeroplane moves with respect to the ground, dividing 400 metres by the number of seconds employed for taking the measures, but, as we shall see, it is not even necessary to make this division, because on one of the sides of the apparatus, which we will describe later, we have a double scale, in seconds and in metres, which gives the result of the division facing the numbers of seconds.

As we have seen, the part of the apparatus which we have described allows us to deduce, by the proper orientation, the real orientation of the motion; and that orientation adding to or subtracting from its proper orientation (counting from the north in degrees in the direction of the hands of a watch, as is supplied by the compass when corrected for magnetic declination, and for deviation due to the iron existing on board) the drift angle, according as it is righthand (that is the effective motion is moved to the right of the axis) or left; and allows the real velocity of the motion to be determined.

Let us note further that the apparatus presents the possibility of plotting out the passage of the points on the ground in another way—namely, by fixing the sight-vane directly to the coupling box and rendering the sight *o* movable in a horizontal plane by means of suitable articulations, supported by the pivot ρ.

It is easily understood how the apparatus itself may be used when it is wished to determine the direction and the velocity relative of the aeroplane, with respect to a movable point on the ground, when it may be supposed that this moves with uniform velocity and in a straight line (for instance, trains, motor-cars, ships) for artillery targets.

Let us now see how we may, by means of the other parts of the instrument, solve the second problem we have mentioned—namely, the finding of the compass indication, which will enable the pilot to follow effectually a fixed route. The following consideration will be useful to us. Let us draw a triangle as shown in Fig. 2, in which AB represents the proper velocity to the aeroplane in size and direction; the included angle will be the drift angle (in the figure, drift on the right). The third side, BC, of the triangle will evidently represent the velocity and the direction of the wind which, combined with the proper velocity, gives us the resultant effective **velocity.** It is clear that the angle ABE (equal to its opposed angle DBC, which is the angle included between the axis of the fuselage and the direction of the wind, and which is called for this reason "head wind" angle) counted in the direction of the hands of a watch from the side AB to the side EB represents the angle through which it is necessary to turn (in the same sense) the proper direction so as to get the direction in which the wind proceeds. So that, knowing the head wind angle, it is sufficient to add it to the proper orientation indicated by the compass in order to obtain the orientation of the wind velocity.

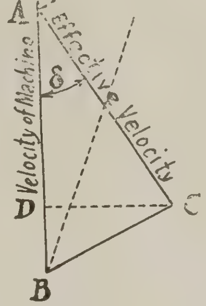

Figure 4

Let us observe in the meantime that the velocity and direction of the wind, obtained in this way, does not vary rapidly in the time (as the soundings by pilot balloons show at least at heights exceeding 500 metres from the ground); so that we may consider the direction and the velocity of the wind as constant within sufficiently ample limits of time. Let us observe, then, that if the route is marked on the map in degrees from the north, the pilot will be certain of passing over it when the angle always counted in the same direction, included between the effective velocity and the direction of the wind ("wind-velocity effective angle") shall be equal to the angle, which may be easily calculated, included between the fixed route and the direction of the wind ("wind-route" angle). Now, the effective wind velocity angle is the angle ACB of our triangle; therefore, if this angle be different from the "wind-route" angle, and hence the fixed route is not followed, we may construct another triangle, A′ B′ C′, which has for sides the velocity of the aeroplane and the velocity of the wind found, and for angle A′ C′ B′ the "wind-route" angle; in this the third side will represent to us the effective velocity with which the aeroplane will cross the fixed route, and the angle at A will represent the angle by which the proper orientation must differ from the orientation of the route (pilotage angle).

Fig. 3 here given represents the triangle A′ B′ C′ for a wind route angle of 90°, the proper velocity and for the wind velocity being the same as before. The angle B′ A′ C′ here becomes 28°—namely, in such a case the direction of the fuselage must differ by 28° from that of the route.

After this let us proceed to examine the second part of the apparatus, which is used to solve the aforementioned problem and which may be considered as an articulated triangle by which the aforementioned triangles may be mechanically produced.

On the base of the apparatus a ruler V is mounted for the purpose of measuring in centimetres the distance from the axis of the pivot ρ to the centre of a platform P that may be slid by the hand along the ruler itself. This ruler is by its construction parallel to the axis of the aeroplane when the apparatus is fixed on board in the way described above; namely, parallel to the direction of flight.

On this we shall calculate the proper velocity of the aeroplane representing metres by centimetres.

However, fixing the platform in such a way that its line of collimation F points, for instance, on the graduation 20, this will signify that its centre is 20 centimetres distant from the axis of the pivot ρ, and so we may say to have calculated the proper velocity of the aeroplane as being 20 metres per second. Round the centre of the platform let a ruler W be movable, and, by an appropriate circular graduation inscribed upon it, we shall be able to read for every position of the ruler W the angle which it forms with the direction of the proper velocity.

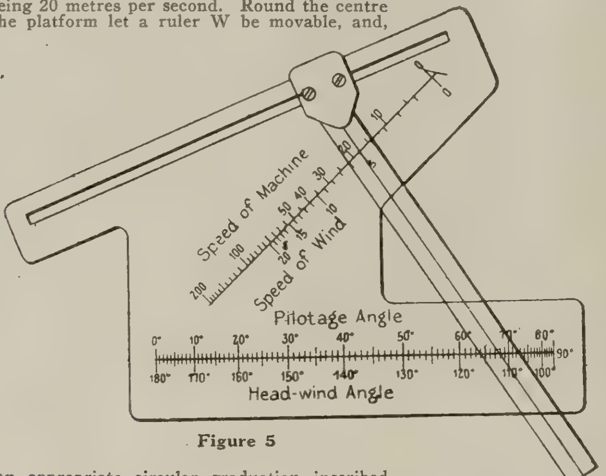

Figure 5

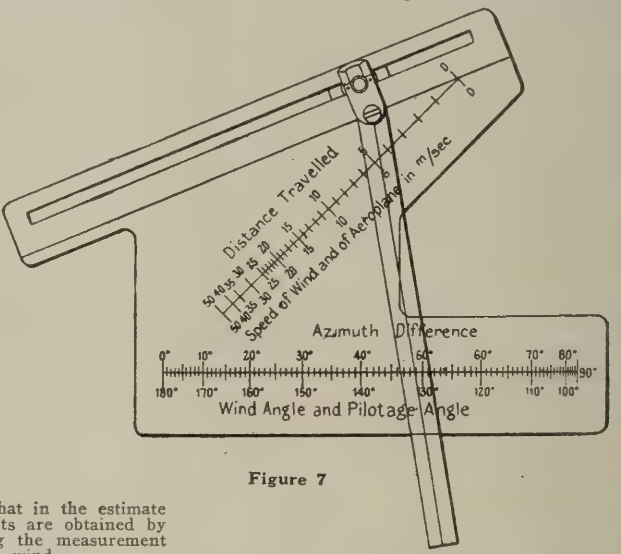

Figure 7

This ruler W also is graduated in centimetres and is provided with a movable hand-slide, opposite to whose collimation line we may read the distance included between the centre of the platform and a certain point B of the slide; another slide is pivoted at this poit, which is again fixed in a third graduated ruler, which can now be described. At the intersection B of the ruler W and the third ruler, a graduated sector is inserted ("crossing sector"), which allows us to know the angle included between the ruler W and the third ruler.

The third ruler revolves round the pivot ρ, and its position shows us the angle which it forms with the straight line which joins the centre of the platform with the pivot ρ—namely, with the direction of the proper velocity by means of a pointer I movable with it and which revolves on the drift sector. This ruler bears two graduations—one in seconds, the other in centimetres, and is the one referred to before which allows us to read, facing the number of seconds used for the measure of effective velocity, the same velocity expressed in metres per second. Therefore, let us call this ruler the *effective velocity ruler.*

It is convenient that at the beginning of every reading, as we shall now show, the ruler W and that of the effective velocity should be placed one over the other. After that let us suppose that we have made a drift measurement as mentioned above; let us place the slide of the ruler of effective velocity on the number of seconds taken for the measurement; we shall get on the ruler itself the segment which represents the actual effective velocity. Let us move the platform so as to reckon the velocity of the aeroplane which we may consider as known, and, always holding the side firm on the effective velocity which was found before, moving it in the opposite direction in such a way that it assumes the orientation of the effective motion—namely, that pointer I is opposite to O of the drift sector; evidently, calling to mind the triangle A′ B′ C′ which we have already mentioned, the ruler will show the direction of the wind, and on its graduation we shall be able to read its velocity. For this reason the ruler W is called the wind ruler. The angle which is read on the graduation of the platform is the head-wind angle, and the angle on the sector at the point of crossing is the wind-velocity effective angle.

As has been said, adding the proper direction to the head-wind angle which has been found, we shall have the direction of the wind velocity. Comparing this direction with the fixed route, we shall get as a difference the "wind-route" angle. Then, turning the wind slide round, but keeping its length unchanged, we may reproduce this wind-route" angle on the sector at the point of crossing. And then, as has been said on Fig. 5, the angle included between the sides of the effective and of the proper velocity (which will be read by means of the pointer on the drift sector put with o opposite the fixed pointer η) will be the angle of pilotage. On the effective velocity ruler we may read the value of such a velocity for the fixed route. By adding or subtracting this angle of pilotage from the direction of the route (according as we read to the right or to the left of the zero of the drift sector) we shall obtain the true direction to be given to the axis of the aeroplane in order to follow the fixed route. From which, taking into account in the usual manner the declination of the compass and the new deviation of the compass, we shall have at once the angle to be given to the pilot.

The detailed examination that I have carried out of the errors which may influence the measurements exposed above shows that the relative error in the measurement of the effective velocity is equal to that in the estimate of the height; the best results are obtained by guiding the aeroplane during the measurement almost perpendicularly to the wind.

All these operations are facilitated by the use of a special plate, on which the above-mentioned operations are indicated, and they become in this way purely mechanical. The apparatus can completely solve the problems pointed out by us in a very simple way. Among the many applications to which the apparatus itself may give rise, I will mention here the following very important one, either for approval tests of aeroplanes or in the case of where the aeroplane's proper velocity is not known and its measurement is needed.

It will be useful to start from the following consideration (Fig. 4). Let us imagine that we know the proper velocity of the aeroplane, and that we have measured its effective velocity and the drift angle, and let us construct the usual triangle $A\ B\ C$. Let us then steer the machine in such a way as to get its proper direction different by 180° from the preceding one, and let us construct the usual triangle $A\ B\ C$ with the new elements. Let us then bring the "proper velocity" sides of the two triangles to coincide, as shown in Fig. 4. By constructing the projections $A\ D$ and $B\ E$ of the effective velocities on the direction of the proper velocity in both cases we shall obtain:

$A\ D$ = proper velocity less the wind propection

$B\ E$ = proper velocity plus the wind projection

Hence $\frac{A\ D + B\ E}{2}$ (Average of the two projections) = proper velocity.

If now, returning to the route indicator, we measure the effective velocity in the above-mentioned two cases, and we construct the projections of such effective velocities along their proper direction (by disposing and fixing the wind side in such a way that it is perpendicular to the side of the proper velocity and then moving the platform in such a way that the ruler of the effective velocity assumes the direction which is due to it, and the effective velocity measured is read on it), the average of such projections will be the proper velocity which was sought.

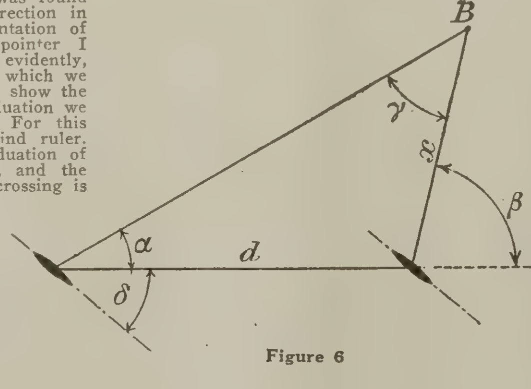

Figure 6

As will be easily understood from what we have before said, it is necessary that during the measurements here described, which will take a very short time, the aeroplane must be kept at a constant height in an unaltered direction by the compass.

The route indicator described above may therefore altogether substitute and complete all instruments in existence up to the present time. We will here refer to the ingenious nomogram constructed by the Goerz firm, which is to be used for rapidly finding out the pilotage angle when the proper velocity, the wind velocity, and the "route wind" (angle measured this time from 6° to 180° to right or to left) are known. Fig. 5 represents instrument in the position of the slide *C*, which makes a wind velocity of 5 metres and a route angle of 68° correspond under the pointer *I*. Leaving the slide fixed, and moving the pointer in such a way that it will pass through the division which represents the proper velocity of the machine (for instance, 60 kilometres an hour) we should obtain on the lower scale the angle of pilotage (about 16°). In reality, however, the Goerz nomogram is of no use, because none of the elements necessary for its use are known *à priori.*

I have, however, effected a slight modification to the apparatus which has allowed me to carry out the following important application of the "Crocco" indicator, measuring the distance of a point on the ground from the vertical line of the aeroplane. The usual pointing instruments solve such a problem only for short distances. Let us suppose that we measure with a sight-vane (for instance, that of the compass) the angle that the eye directed towards the aim *B* forms with the axis of the aeroplane. Adding or subtracting from this the drift angle δ, according as this is on the same side of the point or on the opposite side, we shall have the angle α of the visual with the effective direction of the motion. After a moment we will make a second determination of the above-mentioned angle. The angle β of the figure will be measured. Now, the angle *B* of the triangle formed by the two visual lines and by the route is evidently—

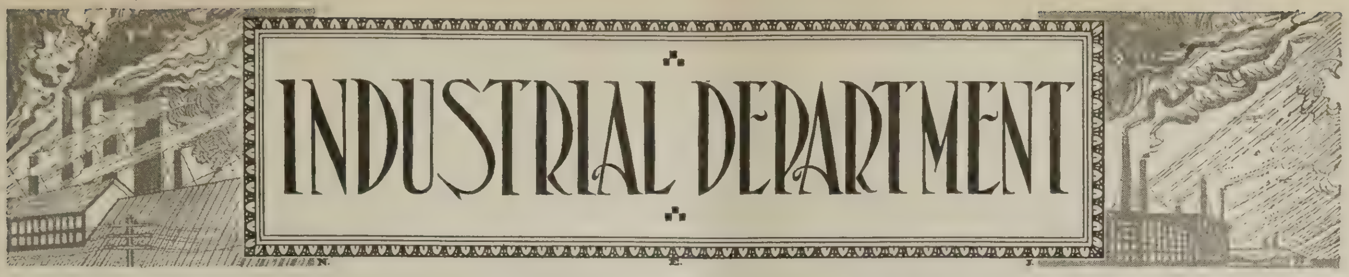
$$\gamma = \beta = \alpha$$

and, calling d the distance passed over by the aeroplane between the first and second determination (which may be immediately calculated when the effective velocity be measured with the indicator), we shall see that the unknown distance x from the second position at the aim should be, as Fig. 6 demonstrates:

$$x = d\frac{\sin\alpha}{\sin(\beta - x)}$$

If modifying as in Fig. 6 the nomogram Goerz we make the transparent pointer I pass through the graduation marked with the distance d and through the angle α, written in the lower scale, and, leaving the slide fixed, we then make the line of the pointer pass through the angle $(\beta - x)$, the difference of the two azimuth readings on the sight-vane, we shall immediately have on the higher scale the distance sought.

The importance of the considerations worked out and of the measurements and applications described will certainly not escape anyone who has any familiarity with the problems of navigation, and particularly the importance of knowing a few minutes before firing the drift, the velocity, and the effective direction of the aeroplane.



INDUSTRIAL DEPARTMENT

PHILADELPHIA IN THE AERONAUTIC INDUSTRY

By W. R. D. HALL

Secretary of the Philadelphia Chamber of Commerce

IN the city where Benjamin Franklin conducted his remarkable series of electrical experiments, laying the foundation for the series of discoveries which have made America the leader of all nations in that line, there has been developed a center of industry having to do with the supremacy of the air. Because of the fact that the United States Navy has one of its principal yards located within the corporate limits of the City of Philadelphia, and because of the further fact that almost within a stone's throw of this navy yard there is an aviation field started at first by a group of enthusiastic young aeronauts and maintained by them as a flying training ground until taken over by the Government, it was entirely within reason that the Secretary of the Navy should select League Island as the location for the Naval Aeronautic laboratory.

This laboratory, about which little has been said as yet because of the necessity for secrecy under the censorship provisions, will be formally dedicated by the Secretary of the Navy on its completion and undoubtedly will be developed into the leading place of its kind in the United States.

Geographically and topographically Philadelphia offers remarkable inducements for the development of aeronautic industry. The city lies on the border line on the coastal plain and the Piedmont Uplands. Northward the Delaware River is navigable for a considerable distance above the city, and southward it extends in increasing widths to the sea. West of the city are the rolling Piedmont Uplands. To the eastward southern New Jersey offers vast level stretches over which flying conditions are ideal.

Long before the development of the present day types of aeroplanes, Philadelphia was the center for experiments in aeronautics with balloons along the Atlantic Seaboard. The ideal commercial location of Philadelphia. "The World's Greatest Workshop," makes it particularly appropriate as a place for future development along aeronautic lines, with the Government Station at League Island and with the development which is bound to come from the increased facilities which will be afforded civilian aeronauts. When peace is restored, Philadelphia will have distinct advantages to offer the manufacturer of aeronautic supplies and accessories within her boundaries.

AERO MAKING IN DETROIT

The Beginnings of an Important Industry

By A. A. TEMPLETON

President, Detroit Board of Commerce

ONE of the principal events of the Detroit Board of Commerce cruise in 1916 was an address by Rear-Admiral Robert E. Peary on the aeroplane as a machine of defense in time of war. He spoke of the "command of the air" as a matter of prime importance in any contest, and emphasized the pitiful lack of this country in that respect. We had then in the army and navy, together, 100 aeroplanes. Little Bulgaria, with an area less than that of the State of Maine, had 300; and in Germany, England and France they were counted by the thousands. He insisted that in view of possible future contingencies, this country should have at least 5,000 planes on each coast, and nearly an equal number on the northern frontier.

The Admiral was considered by some of his hearers as an alarmist, but his address made a deep impression on others, and may be said to have marked the beginning of serious thought on the possibilities of Detroit as an agent of preparedness in this line of service.

There was every reason to believe that this city might attain the same prominence in the making of aeroplanes that it did in the automobile industry. It had a larger force of gas-engine workers than any other city in the country. It had a host of skilled brass, steel, aluminum and wood workers. Its manufacturers had abundant capital, and they had already shown a great readiness in adapting their plants to new conditions. A number of young men had taken up the air flight as a pastime, and they began to seriously consider the possibilities of the aeroplane as a business.

The most important contribution of this city to the industry has been the development of a suitable motor for the plane. One of the persons interested was Mr. Henry B. Joy, president of the Packard Motor Car Company, and the most expert engine workers in that plant were assigned to the work of developing a motor that should have the best possible combination of lightness, strength and speed. Three months of experimentation produced a motor which is still in wide use. Mr. Joy also made another important contribution to the service in turning over to the Government a large tract of land well adapted to aeroplane instruction and training. This tract is famous as the Selfridge Field near Mt. Clemens. The Packard Company is still doing important work in the manufacture of its serviceable motors.

With the entry of the United States into the war there came an insistent demand for aeroplane construction on an even larger scale than Admiral Peary had advocated, and speed as well as volume of work were essential. In the emergency Messrs. Henry M. and Wilfred C. Leland, who had built up the Cadillac motor car industry left their company and incorporated with others as the Lincoln Motor Company. With a speed that was almost magical they built a factory nearly quarter of a mile long, and made arrangements with the Government for the manufacture of the Liberty Motor which has been perfected through the agency of experts from all parts of the country. Within a few months of the inception of this enterprise these motors were turned out in quantity and are the standard motor now in Government construction for overseas service.

There is no plant in the city at present nor any immediate prospect of one for assembling planes. Curtiss Brothers have a small plant for making some of the parts. The Ford Co. are making a motor that is in use for planes in this country, and a large contract has been placed with an auto body company for the wooden parts for frames. Aside from the Liberty Motors, however, aero constrduction has not yet taken place among Detroit's greatest industries.

The direct exports of aeroplane parts from this port commenced in June last and has been continued, though in small volume ever since. They all go to Canada, where the work of assembling planes is far in advance of that in this country.

(Continued on page 62)

FOREIGN NEWS

FRANCE

The French official announcement of March 6th reports the destruction of five enemy machines, as follows:

"On Tuesday three German aeroplanes were brought down by our pilots and two by the fire of our anti-aircraft guns."

Thirteen tons of bombs and successful combats were announced on March 7th:

"On March 6th four German aeroplanes were brought down by our aviators. Our bombarding squadrons dropped 12,000 kilograms (more than thirteen tons) of explosives on railway stations and munitions depots in the enemy zone."

"Allied aviators bombed enemy depots west of Petric and the railway station at Pardovica, in the Vardar Valley," according to the announcement on the Balkan operations issued on March 3d.

Rumors again reach us that Captain Georges Guynemer, the renowned French fighting aviator, who has a record of destroying fifty-four German machines, is not dead but is a prisoner in Germany. It is reported that the entire squadron (Les Cigognes), to which Guynemer was attached, shares the belief that Guynemer was not killed, but captured. The report most recently received is that Guynemer is in a hospital in a German fortress near the Russian lines. Several captured enemy aviators, though not stating positively, assert that it is generally believed that Captain Guynemer is a prisoner in Germany. The enemy has never issued a statement on the subject, and when last seen, Guynemer was not reported in battle with German airmen.

GERMANY

Very successful work on the part of German aviators is indicated in the official announcement of March 7th, which follows:

"Nineteen enemy aeroplanes and two captive balloons were brought down yesterday in aerial fighting. A great many French civilians were killed by British aviators who dropped bombs on the hospital at Turcoing."

GREAT BRITAIN

(March 5th)

"After two days of wind and rain the weather cleared slightly on the afternoon of Tuesday," says the official report of March 6th. "Bombs were dropped on railway sidings northeast of Lille.

"In air fighting two hostile machines were downed and one was driven down out of control. One of ours is missing.

"After dark the Ingelmunster Railway station and an aerodrome northeast of St. Quentin were heavily bombed. All our machines returned."

The War Office communication dealing with aerial operations on the battle front, issued March 7th, says:

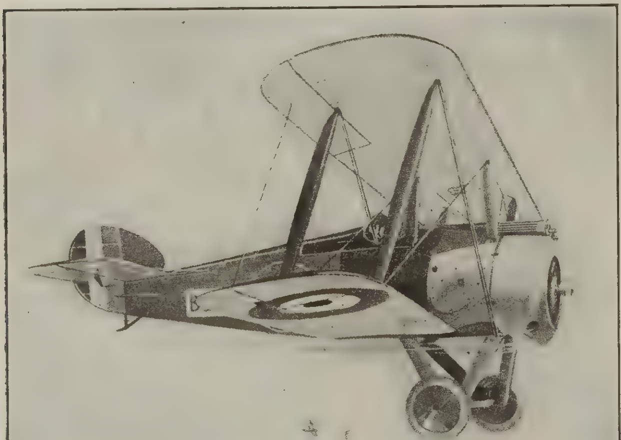
"There was fine weather Wednesday, and great aerial activity on both sides. There was continuous fighting between our scouts and enemy machines, which persistently attacked our bombing and artillery machines.

"Ten German aeroplanes were downed and ten others disabled. Three of our machines are missing."

Allied aerial superiority on the Italian front is freely admitted by captured aviators, says the British announcement issued March 5th, which is quoted below:

"Since the last report the weather has been dull and flying has only been possible one day, on which we destroyed three hostile machines. Captured aviators admit freely Allied superiority in the air, and say that great damage has been done to the aerodromes and machines, especially in the past two months.

"In the past twenty-four hours the weather has become very bad, with storms and snow in the mountains. The usual patrol and artillery activity continues whenever possible."



Sopwith "Camel" fighting biplane

The Germans conducted an aerial raid on London on the night of March 7th, resulting in 11 deaths and 46 injured.

The official statement on the raid said:

"Last night's air raid appears to have been carried out by seven or eight enemy aeroplanes, of which two reached London. The first two raiders approached the Isle of Thanet at about 10:55 P. M. and proceeded up the Thames estuary. Both were turned back before reaching London.

"Meanwhile the third raider came across the Essex coast at 11:20 P. M. and steered west. At 11:45 P. M. it was reported over East London. A few minutes later it dropped bombs on the southwestern and northwestern districts. At 11:50 P. M. the fourth raider, which also had come in across Essex, dropped bombs to the north of London and then proceeded south across the capital, dropping its remaining bombs on the northern district between 12:20 and 12:30 A. M. The remaining enemy machines, all of which came across the Essex coast, were turned back before they reached London. A certain amount of damage was caused to residential property in London. Several houses have been demolished."

In the month of January, says an official statement issued by the War Office on March 4th, the Germans dropped 1,482 bombs in the aera occupied by British troops in France. In the same period British aviators dropped 7,653 bombs in enemy areas.

The Germans dropped only 221 bombs in the daytime, the statement adds, while the British dropped 5,900 between sunrise and sunset.

The Air Board of Great Britain is issuing instructions to manufacturers of aircraft regarding efficient methods of cutting aircraft lumber. Diagrams are circularized showing the correct way of sawing up planks of various grains.

The Ministry of Munitions has assumed control of the supply of tin in Great Britain under the provisions of the Defence of the Realm Act. The immediate result of the measure was a falling off in the market price of tin.

Speaking at the Royal Institution, Professor Pope stated that air photography for military purposes is now being done with the aid of plates sensitive to the several colors of the spectrum.

HAWAII

Major Harold M. Clark, Sig. Corps, U. S. A., who is stationed at Fort Kamehama, H. T., recently made three flights in a seaplane over the island of Oahu, on which the city of Honolulu is located. His report of air conditions was so favorable that a Hawaiian note prophesies that within five years Oahu "may develop into one of the greatest aviation stations of the U. S. Army and Navy," as the climate there is believed to be favorable to flying at all seasons of the year.

ITALY

"The Minister of the Navy," says a diplomatic despatch from Rome dated March 4th, "states that on the night of February 27-28 a squadron of Italian aeroplanes bombarded Pola with two tons of explosives. Hits on the arsenal and other military works were observed. The aeroplanes returned safely to their base, notwithstanding the enemy's fire.

"All Italy is very indignant over the savage brutality shown by enemy aviators during recent air raids over Venice, which had as their exclusive object the damaging of the monuments. Two of the enemy machines fell into our hands. One Albatross was forced to land within our lines. The occupants attempted to set fire to their engine, but were prevented by Italian soldiers, who captured them. One of the enemy officers was found in possession of a plan of Venice."

Bombing of enemy aerodromes is reported on March 6th as follows:

"Our aircraft bombarded the enemy aviation ground at Motta di Livenza and a column of troops marching in the neighborhood of Oderzo. A British aviator brought down a hostile machine."

The official statement of March 7th reports the following aerial activity:

"British batteries and aviators downed hostile aircraft and set fire to two captive balloons. Naval seaplanes dropped two tons of bombs on enemy encampments below Griselera, on the lower Piave."

Professor Pio Foa, of Torino, declared in the Senate to-night there were so many aviaion camps in Italy that the wheat areas were being seriously restricted.

RUSSIA

A Petrograd despatch to the Exchange Telegraph Company, dated March 4th, says that despite the cessation of hostilities, a German aeroplane appeared over Petrograd at five o'clock the preceding afternoon and dropped bombs in various sections of the city, resulting in three deaths, and five injured. This is the first time an aerial attack has been made on Petrograd.

Aeroplanes were seen flying over the Nevsky Prospekt, and the belief prevailed that the enemy was aiming at the Nicholas station.

On the night of March 3d, Zeppelins were observed at Gatchina, thirty-five miles from Petrograd, flying toward the capital, but they were driven off by anti-aircraft batteries.

A delayed despatch describes the part aeroplanes played in the capture of Pskov. It is stated that an armored aeroplane acted as a scout for the German cavalry advancing along the railway. When the aeroplane hovering over Ostrov signalled that the evacuation had begun, the cavalry rushed up at full gallop.

SPAIN

While flying at a low altitude over the Cuatrovientos aerodrome, a Spanish aviator, Captain Souza, dashed into a platoon of soldiers. It is reported that three persons were killed and seven injured as a result of the accident.

A Compressed Air Engine for Model Aeroplanes

For quite some time it has been the desire of model flyers, both in this country and abroad, to find some means of substituting rubber strands as motive power for model aeroplanes. Various types of engines requiring the use of compressed air, steam, gasoline, carbonic gas, electricity, etc., have been offered, but although each in a way has suggested a solution of the problem, perhaps the most promising type of engine is that embodying the use of compressed air.

The Two Cylinder Opposed Type Engine

During the past few years model flyers of inventive ability produced many interesting types of compressed air engines, of which the following types seem to have been most successful two cylinder opposed, three cylinder stationary, three cylinder radial, four cylinder upright and four cylinder radial, opposed. But perhaps of all the different types mentioned the two cylinder opposed has been more often appreciated by model flyers; first, on account of its simple design; second, because of the comparatively small expense involved in its construction, and third, because it has been proven practical.

The making of one of these interesting compressed air engines does not require the use of an elaborate machine shop, but merely a set of simple tools consisting of a file, drill, small gas blow torch and a vise. In laying out the work the first thing that should be done is to secure two fishing rod ferrules (female) for the cylinders and an additional set of ferrules (female) for the pistons, described in a following paragraph. Also purchase another set of ferrules (male) from which to cut the cylinder heads. Such ferrules can be purchased at most any Sporting Goods store. After the ferrules have been gotten, the female ferrules should be filed down until they measure two inches. They should then be cut in from the end ¾ of an inch and again cut through as much as ¾ of the diameter. Fig. 7. For the cylinder heads, cut off the tops of the male ferrules so that they have a depth of ⅛", then through the center bore a hole ⅛" in diameter into which, later on, the intake pipes are soldered. Next solder the heads to the cylinders, using soft wire solder.

Pistons

One thing most essential in making the pistons is that they operate freely, and to do this both ferrules should be rubbed very carefully with a rag that has been saturated with oil and upon which fine powdered emery has been shaken, then, measuring from the closed end ½" cut out both pistons, Fig. 5-a. The connecting rods should be made from brass tubing, each piece measuring 1¼" long by ⅛" in diameter, and to facilitate the boring of a hole at each end, the ends should be flattened. Fig. 6. Through the flattened ends of each rod bore a hole 3/32 inch in diameter. From a solid piece of brass, ¼" in diameter by ½" in length, two studs should be cut, each stud to measure ¼" in diameter by ¼" in length. These studs are to be used in connecting the piston rods to the pistons, but to enable this, both studs should be slotted from one end deep enough to receive the end of the piston rod, Fig. 5-a, after which a hole should be drilled through the stud for the insertion of a steel pin to hold the piston rod in place and yet enable it to operate with ease. The stud with rod connected should be soldered to the head of the piston, Fig. 5-a.

Valve Mechanism and Crank Shaft

One would suppose this section of the engine to involve considerable work, but anyone so thinking need only to ask one who has made an engine of this type to find that it requires only a slight knowledge of mechanics. In making the outside valve mechanism serve as a bearing for the crankshaft as well as a casting, brass tubing ¼" in diameter by 1½" in length should be used. For the valves and exhaust port three holes should be drilled through the tubing, Fig. 4, each hole having a diameter of ⅛" and drilled ½" apart. The valve shaft, also crank shaft, used in connection with this engine also serves as an accommodation for mounting the propeller and is cut from a drill rod 2" long by 3/16" in diameter, Fig. 3. As part of the valve mechanism this drill rod should contain two cuts, one on either side, as illustrated, one cut being 1" from the stud end the other ⅜", both one-half inch by 1/32" deep. The stud end constituting that end to which the connecting rods are attached. However, in order to accommodate the piston rods that they may function properly, a crankthrow is necessary, and this may be made from a piece of flat steel 3/32" thick, ⅜" in length by ¼" in width containing a hole at each end, the holes being ½" apart and measuring 3/16" in diameter.

As shown, one end of the throw is soldered to the end of the crankshaft, while into the other end of the throw is soldered a piece of drill rod ¼" in length by 3/32" in diameter. It is to this end of the throw that the rods are connected, Fig. 1-f.

The Air Tank

A satisfactory tank, one that will serve well for experimental purposes, can be made from a sheet of brass or copper foil 15" long by 1/100" in thickness. By twisting the sheet of metal a cylinder is formed, but must be rendered strong and airtight by soldering the edges together. For the ends of the cylinder or tank obtain two small oil cans, each measuring 2½" in diameter, or the same diameter as that of the tank. But before soldering the cans, now considered as caps, to the ends of the tank, the holes in which formerly the spouts were inserted should be closed and rendred airtight, and to do this two small metal discs can be used, solder being used to hold them in place. An air valve can be made from a bicycle air valve and soldered into one end of the tank, as illustrated, Fig. 2, and for the insertion of a small gascock or outlet valve in the other end a hole sufficiently large enough should be drilled. Before soldering the cock or valve into place render it lighter and more efficient by filing away all unnecessary or surplus metal, Fig. 2.

(*To be continued.*)

Eugene J. McGuirk of Biloxi, Mississippi, designed and built this model. You will agree with us, no doubt, it's a dandy. Because of it's attractiveness and clever design Mr. McGuirk received offers from several large stores in his home town and other cities to loan the model for exhibition purposes. The model measures six feet from tip to tip

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

The Jovial Airman

I "take off" from the spring-y lawn,
I hover with the lark at dawn,
  I rise, I call,
  I glide, I "stall,"
Exuberantly, I fly through space,
My outstretched wings increase in pace,
With early morn I run a race.

I am a swallow on her flight,
I catch the golden-tinted light,
  I "bank," I "loop,"
  I climb, I whoop,
Delightedly, I breathe the air,
I quaff the ozone rich and rare,
And to the breeze my cheek I bare.

I revel in my engine's song,
I watch, and hum my way along,
  I laugh, I sing,
  I shout, I fling
Exultantly the earth away.
I dally, for I fain would stay
And live near Heav'n for one brief day.

I see the mellow tints of morn,
I joy with day so newly born,
  I rise, I glide,
  I climb, I ride
Triumphantly above the rain
That penetrates with might and main
The woods and dells and mountain chain.

I end my flight and caper round,
I gently volplane to the ground;
  I pine, I throb,
  I sigh, I sob,
With nimble feet to earth I spring,
With airy voice I laugh and sing,
My heart and soul have been a-wing!

W. S. T.

New Aviator (first time out): I'm afraid to take this back now. What'll the captain say?

I've been through all the sicknesses,
  Among them 'pendicitis,
When I felt bad, and wanted to be glad
  I read the page, *Aeronitis.*

Sickness was my hobby,
  Best of all was tonsilitis,
But it is nothing, but the stuffing
  Of the real Bird, *Aeronitis.*

Along around my fifteenth year
  I got acquainted with Bronchitis,
For my own sake, they didn't take
  From me my *Aeronitis.*

When I feel angry at the World
  And get an attack of the "Blueitis."
I buy a copy of AERIAL AGE
  And turn to *Aeronitis.*

M. G. G.

Not Much!

The omniscience of the Comptroller of the Treasury is completely ilustrated by the following incident. In a case that came before him for decision appeared the name of a civilian with these initials after it: "I. A. and A. E., S. S. L." Did this stump the Comptroller? Most decidedly not, for he goes calmly on, "which I take to mean Inspector of Aeroplanes and Aeroplane Engineer, Signal Service at Large."

Merely a Banker; An Air Raid Tale

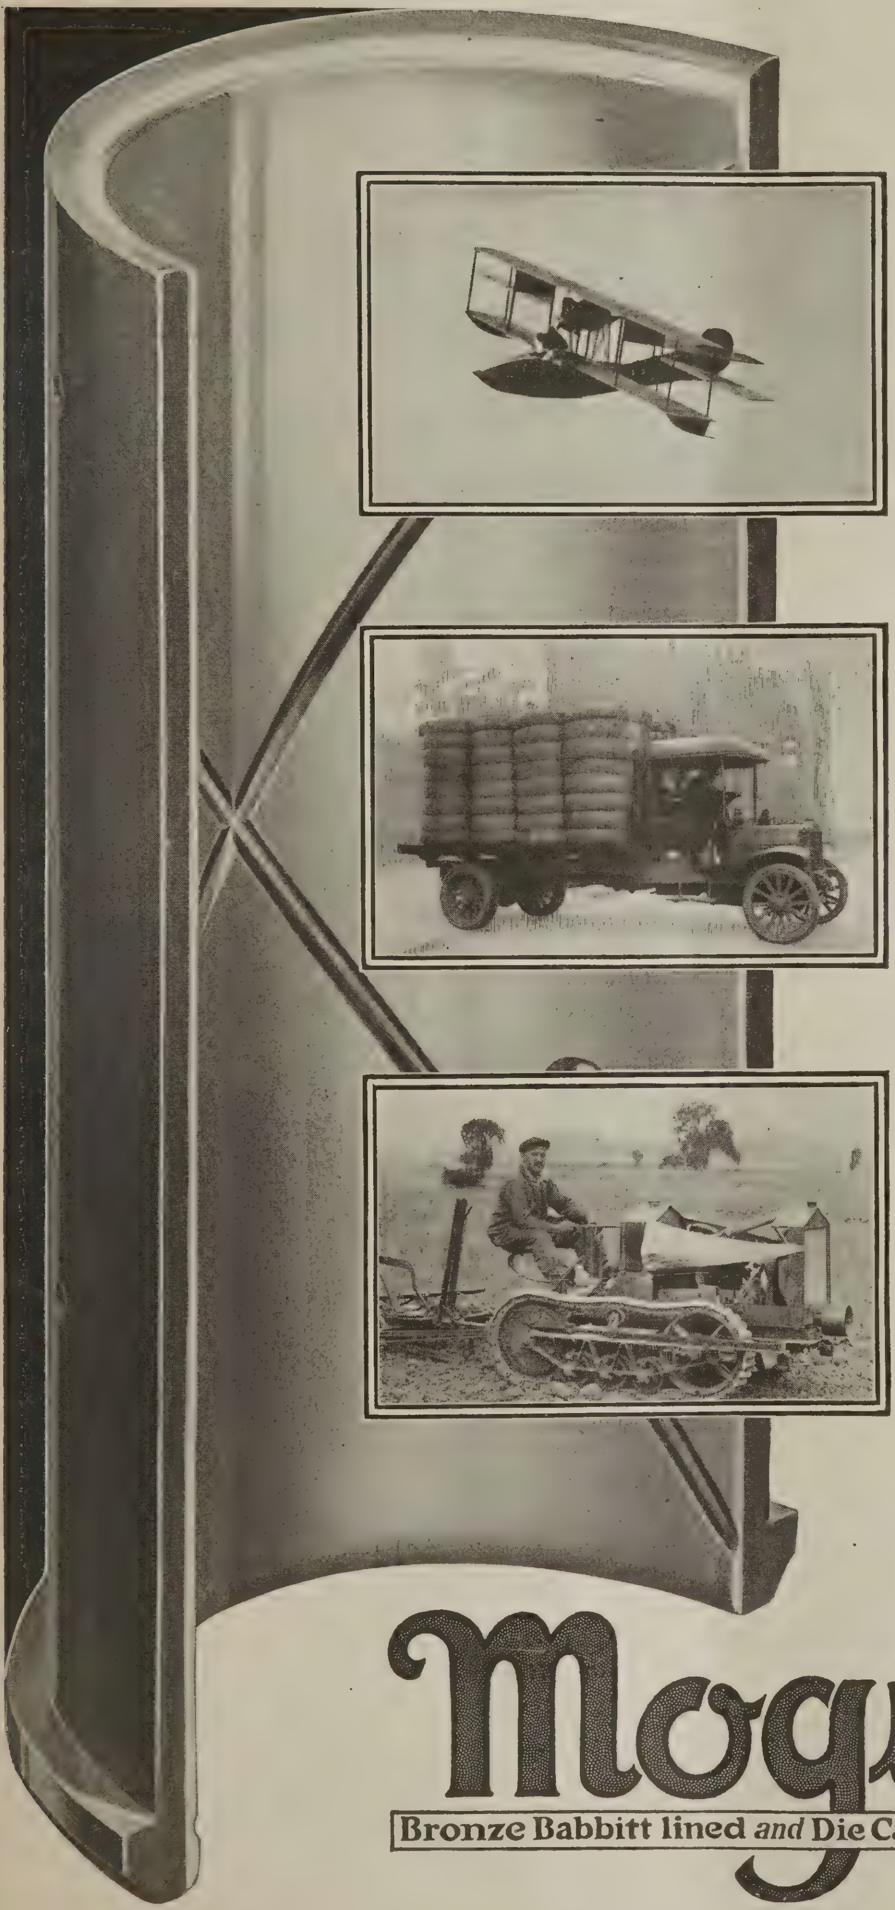
During a German air raid a British three-inch gun mounted on an automobile truck took up its position in a fashionable residential district directly in front of the house of a wealthy banker. The banker stood the racket of the barrage fire for a time but then walked out and said to the officer in charge:

"I say, would you mind taking that thing a little further down the street? We don't like the row and it is fairly shaking our walls."

The young lieutenant was non-plussed for a moment.

"Look here," he finally snapped out, "do you take this for a blooming hurdy-gurdy?"

And the barrage went on.



Mogul Service

The tremendous demand of the country for airplanes, motor trucks and tractors prohibits delays in their manufacture.

In meeting this demand for speed you will appreciate Mogul delivery service exemplifying our motto, "On time or a little bit ahead."

Mogul bearings are now used in leading airplane, truck and tractor engines and thousands of pleasure cars.

THE WORLD BASING POINT FOR PIG-IRON—BIRMINGHAM

By BLANKS EVERETT

General Manager of the Birmingham Chamber of Commerce

BIRMINGHAM, the world's basing point for pig-iron, is situated in the northern half of Albama, but so close to the center that it is regarded as the hub of the State both geographically and by virtue of her gigantic industrial activities. She closely hugs the base of Red Mountain, a mountain of wealth, which stores vast treasures of iron ore, and each year discloses heretofore undiscovered mineral wealth.

The immediate center and business portion of the city is built upon the bottom of the valley, her residence sections spread out toward every point of the compass. On the north magnificent dwellings are built upon a slightly elevated plateau, on the east and west follow the valley, but on the south palatial homes with spacious grounds dot the mountain side and some have been so bold as to top the mountain's peak.

Topographically Birmingham is nearly ideal. The business district is laid off into uniform squares, the streets and avenues dividing them are wide, well paved and numbered. The streets run north and south, the avenues east and West, making the location of any desired point, by the veriest stranger an easy matter. This method of naming the streets and avenues is carried a little way into the residential section of the city, or until the elevations are reached.

Highland Avenue, which is said to be the most beautiful street in the south, gracefuly winds along the mountain, where other fashionable avenues branch from it and gradually wind up the mountain sides, sometimes they disappear over the top, sometimes they terminate at many of the handsome houses now situated there. Good roads and well built driveways follow the mountain top for miles, affording one a wonderful view of the valley and city below with its great population and stupendous industrial activities. At night a view of the Birmingham district from his height is awe inspiring. Myraids of arc lights, huge electric signs and the lamps of the great white way glitter and twinkle like millions of fire-flies. This panoramic view is flanked at each end by the great red-gold glow of the furnaces and coke ovens. At a distance of twenty miles the reflection of other furnaces in the immediate district can be seen.

The Birmingham district stands out, far from all other sections of the state, and the south,—and because of her incalculable wealth of iron ore and coal is one of the important districts in the country at this particular time and is indubitably destined to maintain that position in the future.

Though less than fifty years old, this city has a population, according to the United States census, of more than two hundred thousand. It has the distinction of being the only city in the world to increase its population 200 per cent within five years.

The rapid growth and development is not accidental. It is due to the genial climate, making it possible for the workman to engage in his trade almost every day in the year, the quantity of pure water, the numerous minerals in inexhaustible supply right within borders available and so easy of access that industrial plants of immense proportions offer employment for both skilled and unskilled labor. While this district is distinctly industrial it holds attractions for truck farmers and small shippers of agricultural products, and manufacturers of many kinds of clay, wooden articles cotton cloth, hose and garments.

Birmingham, commercially and industrially is not a typical southern city, its unlimited supply of suitable and cheap material for the manufacture of iron and steel commodities, including armor plate and munitions, its rail and water facilities for distribution of the finished products, its nearness to southeastern Atlantic ports, gulf ports, Panama Canal and Pacific ports, its splendid labor conditions, as evidenced by the successful operation of the steel plants, blast furnaces, machine shops, mines, lumber mills, etc., its proximity to vast undeveloped and potential hydro-electric powers and its location in the midst of enormous coal fields attracts financiers and industrial magnates from the world centers,—all this has made Birmingham one of the most cosmopolitan cities of the world. But,—with all of these thousands of representatives of other parts of America and other parts of the world, one finds the atmosphere of true southern hospitality within her gates.

Birmingham, because of her manufacture of large quantities of machinery gets revenue from improvements and investments made in all parts of the State, from the sixty million Government nitrate plant at Sheffield in the extreme northern part of the State to the big ship building yards at Mobile on the gulf coast.

Because of the limestone, coal and iron ore in this immediate district iron can be, and is, manufactured here cheaper than in any other place in the world, and for that reason is the basing point for pig-iron prices in the United States.

Retail trade comes to this city from a radius of one hundred miles. Wholesale trade extends to adjoining states and foreign trade extends to all foreign countries

Transportation facilities are exceptionally good. Trolley mileage is approximately 150 miles or about the equal to that of the surface lines of New York City. Fifteen miles is the maximum distance of a five-cent ride. Eight of the largest trunk line railroads in the United States enter this city. One of those, the Southern Railway, presents the most unusual situation to be found in any city in the United States, because it has five actual main lines radiating from Birmingham. Besides these numerous trunk lines there are two efficient industrial lines within the district. In every direction going out of Birmingham there are at least three standard, fully equipped trunk lines, and in some cases main paralelling lines.

In a short time water transportation will be a common means of moving products. Already a large consignment of dry goods has been brought from New York to Birmingham by the Warrior River route, at a gratifying rate to the buyer. This river is navigable all the year round.

Birmingham is the home of the National Good Roads Association, the Alabama Good Roads Association and the Bankhead National Highway Association, meaning that the offices of those organizations are maintained here, and many of the strongest advocates for good roads live here.

Twentieth Street and First Avenue is the most highly developed corner in the south. There are more than two thousand occupied offices in the four buildings at the intersection of these streets. Property on the corner of Nineteenth Street and Second Avenue is the most valuable business property in the south. Within the past few years a two million dollar terminal station has been finished. Concrete viaducts are being built over all grade crossings. Large and modern hotels take care of the transient visitors and the largest and most completely equipped apartment houses in the south are located not only in the fashionable residence districts but within short walking distance of the immense office buildings. Housing conditions are generally good and are being improved all of the time. Eleemosynary institutions care for the needy. Many of these occupy and own substantial buildings giving inmates many physical comforts.

While Birmingham's industrial activities cause the eyes of the world to be focused upon her, she is also coming to be recognized as a city of cultural attainments. Among the many national conventions held here during the year, none were more appreciated than the Bi-ennial of the Federated Music Clubs of America.

It was said by the National Playgrounds Association that Birmingham made the greatest progress in establishing and developing her playgrounds and playground system than any other city in the United States. Through the Community Sings, which were inaugurated during the Summer, she has attracted much attention and merited from musicans of note and National music publications throughout the country.

The public school system is considered by educators, with national reputation, to be one of the three best in the country. There are forty-five schools for white children and twenty-one schools for negro children, and appropriations already made for the building and equipment of a half dozen more. Especial attention is given to industrial education and vocational training. The night schools have better attendance than any other night schools in other southern cities.

Besides the very excellent public schools there are thirty-six private schools and colleges, including colleges for young men, young women, medical and dental colleges, sectarian and dominational schools, business colleges and schools of music and art. These various educational institutions operate for the standard school term of nine months with the exception of the business colleges, which are open the entire twelve months.

Five public libraries with adequate help supply those bent on reading for amusement, instruction or research work, with the necessary books and periodicals.

Three daily papers beside many smaller papers are published here. The most modern newspaper plant in the south has just been completed. Among the large buildings is the Jefferson County Bank building, twenty-six stories high, also the tallest building south of the Ohio River. It is built of white marble and stone quarried in Alabama. Banking facilities are commensurate with our needs.

Immense department stores supply the need of this and surrounding territory.

Large and enthusiastic civic bodies are over active in interesting and locating business of all branches for Birmingham and the Birmingham district.

The Food Preparedness and Marketing Bureau of the State has its offices in the Chamber of Commerce Building and has done such splendid work among farmers and merchants that the crops were more than doubled the past year.

All secret and benevolent orders, and labor bodies have local organizations in Birmingham.

The Young Men's Christian Association, The Young Women's Christian Association and the Young Men's Hebrew Association with the Birmingham Athletic Club take care of the physical and moral welfare of the young people.

Birmingham's Country Club is the pride of Alabama. Other promi-

NEW·AERONAUTICAL·BOOKS

Military Observation Balloons

With a balloon squadron to be the first aerial unit in service on the American sector of the front in France, particular interest attaches to this branch of the service, and consequently the book "Military Observation Balloons," by Emie J. Widmer, which has just come from the press is opportune. The book deals with the manufacture, equipment, inspection and handling of military observation balloons. It is based on the balloon manual of the Germany army, including the drill and equipment in use at the beginning of the war. The three plates and 38 illustrations are well chosen. Altogether the volume is one which every student of the aerostatic section of our aviation corps should read. It contains 157 pages of text and costs $3.00 postpaid.

The Lewis Gun

Every aviation cadet should be familiar with the Lewis Machine Gun operation, and consequently should peruse the handbook on "The Operation and Tactical use of the Lewis Automatic Machine Rifle," which is now available, and which sells at 60 cents.

A Useful Encyclopedia

Dyke's Automobile Encylopedia is a book well deserving the attention of the aviator and the air mechanic for, although it does not specifically deal with aviation engines it treats the subject of internal combustion engine in such a comprehensive manner that the working of the stationary aviation engine becomes self-explanatory. The fact that the Signal Corps Aviation School at San Diego, Cal., is using this book in its course of instruction particularly recommends Dyke's Automobile Encyclopedia to the aeronautical student.

The book is not what one might term an encyclopedia in the true sense of the word, yet it is one of the most complete reference works on automobiles published; any subject, trouble, remedy or repair one can think of can be found in the 6,000 lines of index.

The repair subject is, perhaps, the most interesting part of the book. There are 1,189 illustrations and 154 pages devoted to this subject alone. Other instructions cover such subjects as: how to build a repair shop for home or business, and how to equip the shop from small tools to regrinding cylinders. Tire repairs, welding, battery charging, etc., are thoroughly treated. The reader is taught how to use tools; how to cut threads; how to distinguish S. A. E. and U. S. S. threads; how to use and read measuring instruments; how to solder, case harden and repair radiators; how to redesign old cars; how to straighten frames, fenders, etc.

The subject of oxy-acetylene welding is very complete and fully illustrated. The instructions on ignition systems cover the entire field and in a simplified manner which anyone can understand. Instructions on the electric starting, generating and lighting are simplified with hundreds of clear illustrations of diagrams. There are 775 illustrations and 279 pages devoted to electric matters, including the storage battery and ignition subjects. In addition there are two supplements on the Ford and Packard cars, with 91 pages and 332 illustrations, a part of which are printed in two colors.

Military Sketching

"Military Sketching and Map Reading" is a new volume by John B. Barnes, based on an expert knowledge of the subject as taught by the Service School, Fort Leavenworth, and an appreciation of the needs of beginners through his wide experience as an instructor of National Guard Officers and at Officers' Training Camps. Written with a view of self-instruction, with new and original illustrations that explain simply and graphically the points that are usually found troublesome to beginners.

The volume is of handy pocket size and sells for 75 cents.

Telegraph Practice

John Lee, M.A., has done a real service by preparing a book on "Telegraph Practice: A Study of Comparative Method," which might be described as a precis of the international methods and practices in this science. It outlines the fundamentals of telegraph practice in such a way as to indicate differences in method as adopted by different administrations. Price $1.00.

Aero Engine Chart

The aviator cadet who has hopelessly endeavored to conceive the many sources of trouble in his motor will appreciate the chart which Lieut. Victor W. Page, of the Aviation Section, S. C., U. S. R., has prepared. It presents a typical aero engine in part section with all the important components shown and outlines all possible troubles apt to materialize considering the auxiliary groups, such as cooling, lubrication, carburetion and ignition. It is of wall chart size and yet can be readily folded to carry in the pocket. Price 50 cents.

Glossary of Aviation Terms

For our airmen who have to think of the components of their machines in French towns, as well as in English, Lieutenant Page's "Glossary of Aviation Terms" will be very useful. The volume contains lists of common aeronautical terms in English with French equivalents, and in French with corresponding English words so it is equally well adapted to French- and English-speaking aviators. The book is well illustrated, and each illustration shows various parts with both English and French names of same. It is divided in four parts, the words being alphabetically arranged to facilitate study. It is intended that this book be used to supplement the usual French-English phrase books which have no aviation terms. While this book is not a dictionary, illustrations are given to enable one not familiar with meaning of aviation terms to see the actual parts referred to. Price $1.00.

The Gas Motor

Under this title Max Kushlan has produced a small volume which deals in general with the internal combustion engine, with a few chapters specially relating to aviation power plants. The elementary student will find the work easily understandable and a stepping stone to more technical works. It is illustrated with half tones and line illustrations and contains an appendix having reference tables of value. It's complete index makes its contents accessible.

Military and Naval Recognition

For those who desire to recognize the service of our uniformed citizens, Lieut. J. W. Bunkley's "Military and Naval Recognition Book" will be useful. It contains 51 full-page plates, 18 in colors, of all of the uniforms and insignias in the various arms of the service and sells for $1.00.

Cavalry of the Clouds

The reading public of England are familiar with the newspaper articles of "Contact," Captain Alan Bott, M.C., and American readers will enjoy the opportunity of reading of his exploits in the air in his latest book, "Cavalry of the Clouds." Major-General W. S. Brancher, Deputy Director-General of Military Aeronautics in Great Britain, has written an introduction to the volume in which he discusses the changing conditions of strategy through aerial observation.

"Contact" describes in thrilling fashion his many escapades in the air, and while his stories appeal to the layman, there is much real information in the book for the air student and the prospective air fighter. Price, $1.25.

An Officers' Notes

Captain Ralph M. Parker has done the Reserve Officer a real service by putting in book form "An Officer's Notes," which provides information on the many irksome points that daily arise, in the carrying out of his duty and in the issuance of orders. It deals with military law, court martials, furloughs, issue of rations, exercises, discipline, commands, notes on topography, etc. In other words, the kind of information which previously had to be secured from many sources has now been collected and presented in a handy small volume size. Price, $1.25.

Gas-Engine Principles

"Gas-Engine Principles," by Roger B. Whitman, is a guide for the user of the small stationary internal combustion engine. The first chapters explain the principle of operation of the gas engine, and describe in detail the various constructions that are employed in the engines on the market. The remainder of the book is given up to practical explanations of the setting up of a new engine, the economical operation of engines, engine care and maintenance, and explanations of the troubles to which engines are subject, together with their remedy and prevention. The book is written with the greatest possible simplicity of expression. The illustrations are especially prepared line drawings made by the author, each one specifically illustrating some particular point or construction. Price $1.60.

"ROBERTS"
Dependable Aircraft Motors

An efficient, dependable aircraft power plant that offers many distinct advantages to the aeroplane constructor and the aviation school. Possesses those three necessary qualities in an aircraft motor—Reliability, Dependability and Power. The ideal motor for training schools.

Roberts Model 6X, Aircraft Motor—100 h.p.

Specifications:—Two cycle, Water Cooled, Six Cylinder, cast en bloc. Valveless and Gearless. 5" bore 5½" stroke. Absolutely simple in construction. Two Miller Carburetors. Two High Tension Magnetos. Aluminum Base. Drop forged hollow Crank Shaft. Ample sized die cast bearings. Lubrication simple and positive in action. Normal speed 1200 R.P.M. Weight approximately 368 pounds. The Roberts Patented Cellular By-Pass absolutely prevents back-firing. A high grade motor at a medium price.

(*Continued from page* 62)

nent social clubs are The Roebuck Springs Motor and Country Club, having eighteen hole golf course unsurpassed by that anywhere else in the state; the Edgewood Club and the Phoenix Club, the last, a Jewish club, complete the list of the leading social clubs.

Four legitimate theatres furnish the very best of attractions during the theatrical season. Three vaudeville houses furnish high class attractions all the year, and a dozen well lighted and modern motion picture houses give pleasure to thousands daily.

Fourteen parks including two for negroes exclusively, afford ample place for recreation and out-of-door amusement.

Birmingham has Commission Form of Government which has been tried and found to be far superior to the old aldermanic order. Five commissioners, elected by the people, stand at the helm and occupy the watch tower of the municipal ship. A completely equipped modern fire department and alert police system give protection to property and citizenry.

It is not by chance that the United States Steel Corporation recently invested another $11,000,000 in this district in addition to the forty million dollars previously invested by the same concern, nor is it by chance that other million dollar investments are being swung to Birmingham.

This article does not deal with the future of this world important city, for Birmingham is essentially and intensely a city of the present, and there is no doubt as to her future. But should one reason from cause to effect and consider the present city, the cause, then the deduction will necessarily follow that the effect,—Birmingham of the future,—will rival any industrial center of the world.

Without Many Aeroplanes We Cannot Win the War

(Editorial in N. Y. *American*)

THE War Department has asked Congress for $450,000,000 to build more aeroplanes.

Four hundred and fifty million dollars is a great deal of money, but it is very little compared to the amount of money it will cost the country to lose the war.

The country cannot afford to lose the war. It does not intend to lose the war. It is going to win the war.

And for that reason everything that will help us to get enough aeroplanes and enough men to fly in them must be done without delay.

Fighting an army with plenty of aeroplanes is an even battle if the contending army also has plenty of aeroplanes.

All America asks of an enemy is an even battle.

But for one army without aeroplanes to fight an army with aeroplanes is exactly like a blind man fighting an adversary whose eyes are wide open.

The great Italian offensive of the Germans was not undertaken till the Germans had first secured the mastery of the air.

When they had destroyed the Italian aeroplanes they brought up their forces and made their assault.

It was successful, because General Cadorna's troops, deprived of their eyes, could not see what the Germans were doing. They could not tell where the offensive was to be launched, how many troops were being massed, or how heavy artillery was being brought to bear upon their line.

If they had had the same knowledge of the Germans' movements as the Germans had of theirs, they could at least have held back the great advance until help could have been brought from France and England.

In every offensive of the war the first battle has been fought for control of the air, and the side that has secured it has begun the attack.

And always the side that has gained the advantage in the air has done so because it had the most aeroplanes in the air and in reserve.

With more aeroplanes than your enemy it is merely a matter of arithmetic in putting him at least temporarily out of business and utterly blinding him to your movements.

America is better equipped to build aeroplanes than any other nation now engaged in the great struggle.

It has all the material ready to hand. It can build better aeroplane machinery, and American mechanical skill can be depended upon to make improvements more rapidly than any other nation.

But all these resources are useless without money.

Only by great expenditures now can our aeroplane fleet be made what it ought to be.

This is no time for Congress to do any cheese paring.

The War Department has expended wisely all the money given to it by Congress.

We have a great fleet of air fighters under way, and a great army of men to man them under training.

But it will be impossible to have too many of either.

Aside from the absolute necessity in the present war of air observation, there is the tremendous destructive power of an aeroplane fleet which shall be strong enough first to overpower the enemy fleet, and second to make air raids over the enemy country.

Were any nation now engaged in the war able to send forth aeroplanes in fleets of a hundred or two hundred to bomb the

Westinghouse

ELECTRICAL EQUIPMENT & MATERIALS FOR AIRCRAFT

What Bakelite Micarta Means to You

Bakelite Micarta is a remarkable material for various airplane parts—a material of great strength and lightness that will not warp, expand or shrink with age, temperature or moisture.

Bakelite Micarta is particularly adapted to use for braces, truss and guy wire stream line tubes, propeller blades, stays, gusset plates and such engine parts as valve tappets, distributor tubes, clutch plates, timing gears.

Has tensile strength of 19,000 pounds per square inch, with grain. Resists water. Will stand temperature of 140 degrees centigrade. Supplied in tubes, sheets, rods and plates of various sizes and in various grades.

Westinghouse Electrical Equipment for the Airplane

This includes starting, lighting and ignition units, wireless generators, switches, volt meters, ammeters, electric heating devices and various other products.

We can also supply Treated and Varnished Cloths, Bakelite Micarta Papers and Moulded Compounds, Wood-Fillers, Cloth-Fillers, Cotton-Fillers, Varnishes and Non-Acid Soldering Compounds. We invite your inquiries.

This could never have happened—

because of the bearings, had they been built to Hess-Bright standards. But because a bearing did jam—on account of faulty materials—the engine "went dead" and a landing was forced. Experience says that the use of Hess-Bright Ball Bearings will avoid such hazards. For they are as dependable and precise in service as human ingenuity and perfect materials can make them. They have stood every known test—including long and grinding service—with a reserve of wear and strength to spare. Our engineering service department will be glad to furnish data that may serve to solve your problems.

enemy, the war would be short lived. No army on land could compete with such an army in the air. No system of defenses ever devised could withstand such a terrible power.

Congress did wisely to pass promptly and without a question the first great appropriation for an air fleet.

How that money has been spent any Congressman can learn by going to the aeroplane factories, or to any of the fields where strong young Americans are learning the newest and best way of making war.

Under General Squier, who is in command of the Signal Corps, and the Aeroplane Production Board, of which Howard E. Coffin is chairman, the work has gone forward rapidly, and with almost miraculous results.

But is must be kept up. We need at this minute every aeroplane that we have. We shall need thousands more within a few months, and nothing must deter their speedy construction and delivery.

British Methods Conserve Spruce

In order to conserve the supply of spruce, of which a grave shortage exists owing to transportation difficulties, British aëroplane manufacturers are using hollow spars in almost any length, shape or size desired. Spars of all lengths and shapes have already been tested and proved to be equal, and more than equal to the best qualities of the solid wood, according to "The Aeroplane."

The present methods of applying silver spruce to aircraft construction are considered very wasteful, when some fifty per cent. of the wood has to be cut out to get the requisite degree of lightness. Instead of this method of hollowing out, the Robert Young Construction Company are building spars of thin veneers glued together to the desired section, strength and shape, to any length, without joints. No matter what the length of the desired spars may be, no scarfing or other joint is required. These spars are one continuous length of uniform strength. The necessary provision for bolts and all other fixings required for wireless installations, etc., are provided for in the building up of the spar.

The same methods are adopted for building up the heavy bearers for engines, etc., and this is accomplished in a more satisfactory form than can be done at present with solid wood.

The struts and spars are all reinforced in their interior construction in such a way as to give the greatest assistance to all stresses and strains without adding to the weight. The most searching tests have proved that these hollow spars give a greater efficiency than any solid silver spruce spar. They have successfully passed the humidity tests, and are reliable in all climes.

This method of construction is the property of the Hollow Structure and Aircraft Company of England, and the Young Company is the exclusive licensee.

Chanute Field News

Three aero squadrons have been sent to Chanute Field for training within the last few days.

"The "Black Bird"—the only black painted machine known—made its first flight at Chanute Field with Lieutenant Smith at the helm. This aeroplane belonged to Lieutenant Schroeder, who is instructing at one of the southern fields. In the machine Lieutenant Schroeder turned 31 loops at the Chicago Liberty Loan demonstration.

The addition of sixteen medical men to the staff at the hospital has increased the personnel of this division to forty-four.

American Aviators Win Mileage Record

Flying an aggregate distance of 35,000 miles in seventy-two hours, aviation cadets at the Rockwell Field, Worth Island Flying Schools, have all records for American aviation training mileage it was announced tonight. The number of machines used was not divulged, but the mileage was attained without the breaking of a single wing section or strut.

For the first time here Sunday flying was permitted today.

General Hoare Injured in Forced Landing

Gen. C. G. Hoare, supreme commander of the entire British Royal Flying Corps in Canada and the United States, narrowly escaped death, but was injured severely about the face and head in a forced landing at Hicks Aviation Field several days ago.

Northern France Scenes Reproduced at Great Long Island Flying Camp

The ground at Hempstead Plains, L. I., is being cross-hatched with concrete ditches, yellow roads and trenches preparatory to reproducing 20,000 acres of northern France as it appears today for the benefit of Uncle Sam's student aviators.

The first contingent of the fliers who are to complete their training there during the next few weeks arrived at Hempstead yesterday. It is expected that their numbers will be increased with the arrival of each train coming from Texas, Louisiana and other southern states in which there are aviation camps, as all are being emptied into the Long Island finishing school.

Before the close of the summer it is expected that Long Island will be one great training camp for fliers, with Hempstead Plains and its faithful reproduction of a section of northern France as its center. Spring and summer months will find Long Island the most nearly ideal spot in the United States for training, the experts declare, and the trainers expect to make the most of these months.

The section of Long Island being camouflaged as a French firing line will be used by the fliers for observation work, including aerial photography. From the point in the sky where photographs of enemy trenches usually are made in war time, it is said that the lines upon the ground will be identical with those to be seen in actual service on the other side of the Atlantic.

Books for Our Soldiers

Good books are urgently needed for our soldiers and sailors here at home in the training camps, on transports, in the navy and over seas in the trenches.

A fund of $1,700,000 has been raised by the American Library Association, to build and equip thirty-four libraries in the camps, to provide trained library service and to buy books. The service includes all Y. M. C. A., K. of C. and Y. M. H. A. huts, hospitals, Y. W. C. A. hostess houses, and many other distributing agencies. The work has grown wonderfully, and to supply the unexpectedly great demand for books and thriftily save the fund, the American Library Association calls for a Book Drive Week, March 18-23, for gifts of books from the people's own libraries.

These libraries need a wide assortment of good books—books of American history and biography, books about the war, about France and for learning French. Poetry is very popular and fiction is in constant demand. Thousands who do not know enough of our language to understand their officers' orders need books on learning English and simple books. Books in foreign languages, too, are greatly appreciated, for men of every nation are fighting in defense of our common country. Books of almost every kind are having a circulation almost unparalleled. Crowds of earnest young fellows who never read before are reading now. They are studying ambitiously to fit themselves for higher duties in service, to help win the war, and for their own advancement after the war. "It's a school!" cried one enthusiastic boy in khaki.

New York must find hundreds of thousands of books. Multitudes of good books that would be of the greatest service are standing unused on shelves in our homes. Others that are treasured would still be gladly given if the great need were known. Fiction is particularly acceptable, for though in less demand, the need of it is imperative to many a lonely fellow, and the funds of the American Library Assocation are restricted as far as possible to the purchase of more serious works and of scientific books, the latest editions of which alone have any value.

Kansas Aircraft Corporation Formed

A new corporation is to erect a factory in Kansas City for the production of aeroplane propellers. A site for the plant was purchased from the Auto Land Company, and the factory now located there will be converted within a few weeks. Mr. J. A. Fullerton, formerly general manager of the Automatic Bookkeeping Register Company, is financing the new corporation.

Bill to Commandeer Timber, Timber Lands and Lumber

The Military Committee on March 1 ordered a favorable report on the Chamberlain bill, empowering the President to commandeer timber, timber lands, and lumber for the use of the Army, Navy, Shipping Board, and the Aircraft Board. Director Gifford, of the Council of National Defense, was before the committee for two hours in secret session for the purpose of discussing progress in aeroplane construction and the supplies of spruce imber available for that work.

VOL. VII NEW YORK, MARCH 25, 1918 No. 2

AMENDMENT TO CUT ARMY AVIATORS' PAY DEFEATED

THE proposed amendment to cut the aviators' pay has met the fate it deserved. It was defeated by the Committee on Military Affairs of the Senate on March 14th.

The Aero Club of America, representing the parents of the thousands of Army aviators under training and the Army and Reserve officers, presented the case for the Air Service. The Club found out that there was a misconception among Army officers, outside of the Air Service, and in Congress, regarding the dangers in aeronautics, and regarding the needs of aviators, and undertook to correct it, by presenting a formidable array of pertinent facts on the subject.

The case was so clear that most of the officers of other branches of the Army than aeronautics agreed that it would be unfair to cut the aviators' pay.

The amendment providing for the cutting down of the aviators' pay was part of Senate Bill 4013, introduced by Senator Fletcher in the Senate and by Congressman Dent, Chairman of the Committee on Military Affairs, in the House of Representatives.

The proposed amendment read as follows:

"Sec. 12. That all of paragraphs one and two of section three; that portion of paragraph three of section three reading 'each aviation enlisted man, while on duty that requires him to participate regularly and frequently in aerial flights, or while holding the rating of aviation mechanician, shall receive an increase of fifty per centum in his pay'; and that further portion of paragraph three reading: 'Provided further, That there shall be paid to the widow of any officer or enlisted man who shall die as the result of an aviation accident, not the result of his own misconduct, or to any other person designated by him in writing, an amount equal to one year's pay at the rate to which such officer or enlisted man was entitled at the time of the accident resulting in his death, but any payment made in accordance with the terms of this proviso on account of the death of any officer or enlisted man shall be in lieu of and a bar to any payment under the Acts of Congress approved May eleventh, nineteen hundred and eight, and March third, nineteen hundred and nine (Thirty-fifth Statutes, pages one hundred and eight and seven hundred and fifty-five), on account of death of said officer or enlisted man' of 'An Act to increase the efficiency of the aviation service of the Army, and for other purposes.' Approved July eighteenth, nineteen hundred and fourteen (Thirty-eighth Statutes, page five hundred and fourteen); all of section six, and that portion of section seven reading: 'Provided, That balloon mechanicians shall receive the same increase of pay as now prescribed by law for aviation mechanicians,' of 'An Act to authorize the President to increase temporarily the Signal Corps of the Army, and for other purposes', approved July twenty-fourth, nineteen hundred and seventeen (Public, Numbered Twenty-nine, Sixty-fifth Congress), and all other Acts and parts of Acts providing ratings as junior military aviators, military aviators, junior military aeronautics, and military aeronautics, and providing increased rank and pay for officers or enlisted men in the aviation section of the Signal Corps and porviding for any other increased pay for engaging in aerial flights, and porviding increased allowances to dependents of officers or enlisted men dying as the result of engagement in aviation be, and the same hereby are, repealed."

Following this action by the Senate Committee on Military Affairs, the following statement was issued on behalf of Secretary Daniels, who had also asked for the cutting down of the pay of aviators:

"Navy aviators hereafter will be required to make a certain number of actual flights to be eligible for the customary fifty per cent bonus in pay under regulations signed by Secretary Daniels today. The number of flights required was not made public.

"In announcing this new policy of the Department, Secretary Daniels said he had reversed his stand taken in a letter to the House Naval Committee recently, in which he recommended abolition of the bonus. This was due largely, he said, to the decision of the Senate Military Committee not to eliminate from the military bill allowance for a similar bonus for army aviators.

"As a matter of principle, I am still opposed to the bonus in pay for aviators," said Mr. Daniels, "but I am told that England maintains the practice, and now that the War Department's position in the matter has been settled it would not do for the Navy to take a contrary course.

"Another fact operating against a change is the number of men who have entered the aviation service under the impression that certain rates of pay would be received."

Mr. Daniels also announced that he recently had asked Congress not to act on his original recommendation for the elmination of the bonus for navy aviators unless similar action was taken with respect to the army. He suggested that the whole question be postponed until after the war."

DELAY IN AIRCRAFT PROGRAM MADE PUBLIC

FURTHER details of the delay in carrying out the aircraft program were made public on March 18, following consideration of the subject by the Senate. Several weeks before the publication of these details the subject was brought forcefully to the attention of President Wilson by the aeronautic authorities and prompt steps were taken to consider the whole subject and make plans for the possible extension of the whole program.

This work has been, and is being, done by several groups of officials and civilians. Some of the details regarding the delay in the aircraft program are given in the following statement printed in the New York *Times:*

"President Wilson has become so concerned over what has been told him of conditions affecting aircraft production that he has set to work a special committee, under the Chairmanship of H. Snowden, Marshall of New York, to collate the facts, with a view to remedying the deficiencies that have been discovered.

Walter S. Gifford, Director of the Council of National Defense, has been made Director of the Aircraft Production Board, a new office. The official announcement ,made on March 12, did not indicate how intimately Mr. Gifford's new position was connected with the revelations of aircraft delay.

"He will deal particularly," said the announcement, "with the problems of organization involved in the activities of this body in its advisory relations with the War and Navy Departments and with the industries involved in the Government program."

"The impression now prevails that the entire military aircraft program will be carried out under civilian direction.

"It is recognized that those with whom responsibility for aircraft production rests have not been entirely at fault. Collision between the aircraft interests and other Government activities in obtaining sufficient quantities of the necessary high-grade timber, labor troubles, the breakdown of transportation facilities, attributable in part to extraordinary weather conditions, the necessity for enlarging the number of cylinders of the Liberty motor to produce the best results in speed—these are some of the things that have caused the delay.

"But men in Congress who are anxious to win the war are alarmed at the condition concerning aircraft production of which they have been made aware. To the credit of some of those concerned in the administrative end of the program, it should be said that they have been frank and have not attempted to conceal the ugly facts. It is felt by some of those whose ideas of duty rises above all other considerations that a resumption of the investigation of the war administration by the Senate Committee on Military Affairs, with particular reference to the aircraft situation, would serve a good end, even if the widest publicity were given to the evidence of inefficiency or whatever it is that has produced the condition that made one Senator, after listening to testimony of how little had been done, put his head on the committee table and weep from disappointment and chagrin.

Situation Told to President

Revelations which led to the present effort to bring improvement were made to the Senate Committee on Military Affairs. On March 1 the committee held a meeting and decided that the delay in aircraft production was so serious that the matter ought to be laid before President Wilson. Some of the committeemen, expressed the belief that the President had been kept in ignorance of what the situation was. On the following day the information that the committee had obtained through an authoritative source was made known to the President, and it is believed that the changes ordered and in contemplation in connection with the failue of the construction program are the outcome of what was said to the President.

The delays in production affect bombing planes. There are plenty of training planes, and no complaint exists on this score. But bombing planes are urgently needed. The fact that General Pershing permitted correspondents of American newspapers with the American expeditionary forces to send dispatches referring to the disadvantage under which the American troops were placed by lack of aircraft carried a significance that was not lost on Washington. Dispatches of this sort were sent from the American front in France on several occasions. They pointed out that German planes flew over the American lines practically without interference.

"A much better relationship between the executive branch of the Government and that part of the legislative end having to do particularly with war measures was established when members of the Senate Committee on Military Affairs attended a session of the War Department's interdepartmental war council last week. It was felt that a new era in team work was beginning and that even the discouraging things learned at that joint meeting were in themselves encouraging in the frank willingness of Acting Secretary of War Crowell and the military officers present to tell the facts without concealment.

"At the same time the emissaries from 'the other end of the avenue'—the members of the Military Committee—found that what they had heard previously was little worse than the new information. They were told at the War Department that the aircraft program was 74 per cent behind, which was understood to mean that only a trifle more than one-fourth of the program of production set for this time had been carried out. What they had heard before they were invited to the War Department was that the percentage of production was lower. The exact figures of the number of aircraft planned for, promised under revised estimates and actually to be delivered within the specified time, and the percentages of production and delay, are withheld from this dispatch.

"The hope has been expressed here that by his personal visit to the American front in France and the opportunity to consult General Pershing and other officers Mr. Baker will learn intimately just what condition confronts our troops through the lack of aircraft and will be better prepared, when he returns home, to take steps to remedy the defects. A feeling exists that in applying the remedy some injustice may be done to men who have worked hard and faithfully, but whose accomplishments have not squared with promises and preliminary rata of a most impressive character.

"Every one here who is in touch with the enormous task that has confronted and is confronting the several branches of the Government engaged in war preparation realizes how much easier it is to criticize than to praise. There is a disposition among those so informed to give credit for overcoming the vast difficulities encountered.

"At the same time it is felt that fault exists somewhere with reference to the slowness of aircraft production."

Criticism along this line goes back to the old complaint of lack of co-ordination, of teamwork, at the top. The criticism would be less severe and the disposition to excuse more general if it had not been that everybody concerned, including Cabinet officers and members of the Military Committees of Congress, were led to believe that, whatever shortcomings in war work existed elsewhere, they did not apply to the program for giving the United States and its co-belligerents the mastery of the air on the French front within a short period."

Aero Club of America States Situation Can Be Saved by Appropriation of $3,000,000,000

THE aircraft situation was discussed at a special meeting of the Executive Committee of the Aero Club of America on March 19. Officials of the Club were asked by the Government several weeks ago to give their advice in speeding up the aircraft program, and an exhaustive report was prepared on request, giving every aspect of the situation.

The officials of the Club would not discuss this report, nor the reported shortcomings or mistakes of men connected with the conduct of aeronautic affairs in Washington or elsewhere.

The following statement was issued after the meeting of the Executive Committee of the Club:

"The situation has many different aspects and it takes people who are familiar with aeronautics and with the military and naval situation in Europe and can give from twelve to sixteen hours a day to the subject to consider every angle without losing themselves in the maze of purely technical details and becoming confused.

"The situation must be considered from the standpoint of whether we as a nation are today going as far and as fast as we can with the aircraft program, and whether the present program is sufficient to insure the constant production of aeroplanes in sufficient number to supply the American aviators in France, train and equip the thousands of aviators under training and to be trained, and contribute to the building of the Allies' forces, so as to gain and maintain the Allies' supremacy in the air.

"If we look at the situation from this standpoint we find that they are only doing one-fifth of what we should do and the main reason is that there are no funds with which to do more. The Government aeronautic organization today is unable to go further essentially because it lacks funds.

"The present aircraft program was made at the time when Italy was victorious and Russia was still fighting energetically. The $640,000,000 appropriation represented the rock bottom minimum cost for the smallest plan that could be made to meet the situation successfully then. It did not allow a margin to take care of changing conditions, and meet unforeseen needs.

"The Italian reverses and the Russian collapse created new conditions, to meet which, we should immediately have tripled our aircraft program. The Club officials consulted some of the authorities about it and found that they felt the same way. But Congress was not in session, and nothing could be done, outside of making plans.

"These plans were made public in part when the War Department made public the fact that the estimates include an item for pay of 11,941 aviation officers and 153,945 enlisted men for the Aviation Section of the Signal Corps. As it takes an average of two aeroplanes to train each aviator to the high point of efficiency required today, and then it takes a minimum of six aeroplanes per aviator to keep him fighting for a year, and it takes a spare motor for every motor used, there would be required 80,000 aeroplanes and more than twice that number of motors. Also a much larger number of schools for aviators and mechanics than there are now.

"To carry out this program would take an appropriation of about $3,000,000,000, or about five times the amount the authorities have had to work with.

"This is a large sum, but it is small compared with the cost of the war, which is about $500,000,000 a day, including economic loss due to cessation of commerce, and the enormous destruction of life and property.

"The Aero Club of America officials went over these figures with different Government officials and they agreed that such a program was necessary—and they felt that Congress would give the necessary appropriations soon after convening.

"This has not yet been done and the Government aeronautic organization's hands are tied until Congress allows further appropriations.

"Provided ample funds are allowed, the situation can be saved even at this late hour and the production of aircraft, motors, and equipment quadrupled in the coming few months—there being a substantial foundation to build on."

THE NEWS OF THE WEEK

Baker Arrives in France

Newton D. Baker, the Secretary of War, has arrived safely at a French port en route to the headquarters of General Pershing, on an important tour of military inspection and conference.

Pennsylvania Aero Club Opens New Library

The Aero Club of Pennsylvania has opened a library at 717 North Broad Street, Philadelphia, where the Y. M. C. A. Aeroplane Mechanics School is located.

The Club was consulted by the Post Office Department regarding the location of the landing place for the new Aerial Mail Route. League Island Navy Yard was designated as being the most suitable, but on further investigation it is found that another site must be selected.

The members of the Club will be the guests of the Engineers' Club when Mr. Howard E. Coffin, the Chairman of the Aircraft Board, delivers his address on "Aeroplanes in the War."

With Our Aviators "Over There"

Thomas Hitchcock, Jr., of Westbury, L. I., serving in the Lafayette Escadrille, disappeared while pursuing an enemy plane over the German lines. A cable later received states that Hitchcock had been captured in Germany and was unhurt. Although only seventeen and on the front but two and a half months, Hitchcock has downed three German planes, two of which he destroyed in one day, and has been awarded the Croix de Guerre.

W. C. Winter, Jr., of Chicago, also with a French aviation corps, was killed in an aerial fight, and fell within the German lines.

Sergeant Wellman, of Cambridge, Mass., serving as an aeroplane pilot is credited with having shot down two German machines on one afternoon. He is a volunteer with the French Aviation Corps.

First Lieut. Robert M. Olyphant, Jr., is now on the French Front. Lieutenant Olyphant was one of those who took up aviation as a member of the First Aero Company, the training of which was paid for at private expense under the auspices of the Aero Club of America. Robert Olyphant, Jr., is a graduate of Yale University, and a member of the Aero Club of America.

At the suggestion of a member of the St. Albans Committee for the sale of War Bonds, an American aviator flew to Childwickbury, the residence of the well-known financier, Jack Barnato Joel, with an application form inclosed in an envelope and weighted with lead. Swooping low he made an excellent drop, and delivered the letter practically on the front doorstep. Mr. Joel responded, and that night sent a check to the St. Albans Association for £25,000.

A two-seater German aeroplane engaged in carrying out observations over the American lines north of Toul was shot down by French anti-aircraft guns on March 10th.

The aeroplane struck the earth near the American first line trenches, falling into a shell crater which caused it to overturn, hiding the big black Maltese cross, the insignia of German aircraft.

There was much air activity all day Sunday and the troops saw many thrilling contests, but found it hard to distinguish between friend and foe, so great was the altitude.

An American aerial observer, in a French aeroplane crossed the German lines on March 14th at a low altitude and used his machine gun effectively on the second line. Other Americans were in the air all day, many over German territory.

One aerial battle is reported. The American observer emptied a gun at a German plane, but without apparent result, as the enemy was hurrying toward the rear. Another machine in which American observers were manning the guns went up to meet German aeroplanes, which had crossed the lines, but failed to get close enough to shoot with any chance of scoring a hit.

Paul Frank Baer, member of the Lafayette Escadrille since January, 1917, brought down his first German aeroplane. Baer served with the Pershing expedition before he joined the Frnch service.

Arthur W. Woods, former police commissioner of New York City, is now a lieutenant-colonel in the Aviation Section

Survey Committee Named on Aeronautical Work

The War Department authorizes the following:

In line with the general policy of the Secretary of War to keep thoroughly advised of the detail workings of the various departments of the Government and with the industrial conditions involved in the consummation of the various war programs, announcement is made of the appointment of a committee consisting of Mr. Snowden Marshall, of New York; Mr. Edward Wells, of the Babcock & Wilcox Co.; and a third whose name will be announced later.

This committee will make a broad survey of the Government aeronautical program with particular relation to the industrial phases of the work.

It is felt that the advice of this committee will prove of the greatest aid in pushing the development of the air service.

Castor-Oil Seed in Italy

Consul Honey, at Catania, Italy, reports: The minister of agriculture has made an appeal to the Province of Catania to take up the cultivation of ricinus (castor-oil seed). The ministry will furnish the seed and will buy the shelled product at 250 lire and the unshelled at 160 lire per quintal. The quintal is 220 pounds and in normal times the lire is worth $0.193. The oil is to be used for the Government's aviation machines.

Liberty Motor for Seaplanes Proves Success

America's first fighting seaplane equipped with Liberty motors has been tried and accepted. A number of the craft are now being delivered for the use of the Naval Air Service. They are the advance guard to a big fleet which will be added to the forces engaged in submarine hunting in the war zone.

A second type of fighting plane for the American army, known as the Bristol model, also has now reached the production stage and a considerably number will become available during the present month. Still another type, a two-seated machine is being constructed.

Navy Aviators Will Continue to Get Bonuses

Navy aviators hereafter will be required to make a certain number of actual flights to be eligible for the customary fifty per cent bonus in pay under regulations signed by Secretary Daniels. The number of flights required was not made public.

In announcing this new policy of the department Secretary Daniels said he had reversed his stand taken in a letter to the House Naval Committee recently, in which he recommended abolition of the bonus. This was due largely, he said, to the decision of the Senate Military Committee not to eliminate from the military bill allowance for a similar bonus for army aviators.

LA FAYETTE FLYING CORPS

In recognition of the services rendered to France and her Allies for the cause of humanity this certificate has been issued to The Aero-Club of America who served during the European war in the capacity of Collaborators to the Corps

Thereby, in a measure repaying the great debt which America owes to France and contributing to the victory of Liberty and Civilization over military Autocracy and Barbarism.

Honorary President — President — Vice President

The Aero Club of America is proud of this certificate presented by the Lafayette Escadrille in recognition of the service it has rendered aviation.

Air Police for New York City

As a part of the newly organized police reserve, formerly the Home Defense League, of which Rodman Wanamaker, Special Deputy Police Commissioner, is to be the head, there is to be organized a division of air defense, according to reports current at Police Headquarters. The police reserves, if the reports are accurate, also will include a mounted squad and a harbor squad, in addition to the regular reserve patrolmen with their olive drab uniforms and campaign hats.

Police officials declined to comment on the new organization, but from conversation with several who have been conversant with the plans it was learned that Commissioner Wanamaker is highly enthusiastic over the proposal to develop police aviators. It is expected that the mounted part of the police reserve will be drawn from those who own riding horses, while the harbor squad will be made up of those who own motor boats.

Non-Flying Units at Full Strength

Sufficient recruits have been obtained for the non-flying units of the aviation corps and the War Department ordered recruiting stations to discontinue temporarily accepting men for this service. As soon as additional units are organized recruiting will be resumed.

Bristol-Curtiss Aeroplane has Successful Test

The Bristol-Curtiss fighting biplane, equipped with a Liberty motor, was given a successful test at Curtiss Field, Buffalo, N. Y., recently. Quantity production of the aeroplane, with slight changes in construction, will be under way this month.

Lieut. Nungesser Now French Aviator Idol

Lieut. Nungesser, who became the French "ace of aces" after the death of Capt. Guynemer, has just brought down his thirty-first enemy machine, according to a news dispatch.

News of his latest exploit is hailed with delight by the French press, because it comes after months of comparative inactivity on his part, during which he has been recuperating from effects of serious injuries received in an automobile accident.

Nungesser's ability as an aviator, coupled with his many injuries and remarkable recuperating powers, is gaining for him the title of "superman."

He has been repeatedly injured, and twice French physicians have classified him as "unfit for further service," but his robust constitution and strong will power have enabled him to overcome all obstacles, and he has steadily found his way back to the escadrille.

During one of his periods of "convalescence", at Dunkirk he brought down nine enemy machines.

Lieut. Soulier, Veteran French Ace, Arrives to Instruct American Troops

Lieutenant Constant Soulier, a French ace, with fifteen German aeroplanes to his credit, has come to the United States to assist in the theoretical and practical insruction of flyers of the American air forces, preparatory to service abroad.

For more than two years he has been in the French Flying Corps and of late has been attached to the Twenty-sixth squadron. He has fought in many sectors.

Lieut. Dodge to be Sent to France

Lieut. Percival Dodge, a prominent member of the Aero Club of America, and long known for his enthusiasm for aviation, is now awaiting orders to proceed to France to join the American flying forces on the French front. Lieutenant Dodge gained his commission as an expert aviator some time ago. After training at Miami, he was sent to the Washington Aviation Section, and is now awaiting final orders.

Lieut. Dodge is a graduate of Yale University. His two brothers are serving in France, one with the American ambulance and the other with the American Distribution Service.

Johns-Manville Erects New Building

The H. W. Johns-Manville Company has erected a modern fireproof building in St. Louis, constructed as far as possible of Manville products. Comfortable arrangements are provided for employees and the building affords excellent facilities for displaying the extensive line of Johns-Manville Asbestos products.

Donald McGee, Civilian Instructor Has Fatal Accident

Donald McGee, identified with aeronautical activity, since his boyhood, met with death at Selfridge Aviation Field recently. At the outbreak of the war he endeavored to enlist in the Aviation Section, but owing to a serious operation, he was rejected. He was, however, accepted as a civilian instructor, and was killed in the performance of his duty at Selfridge Field.

Mr. McGee constructed his first successful aeroplane at the age of nineteen. He was elected a member of the Aerial League of America just prior to his unfortunate accident.

Miss Katherine Stinson, who holds the American duration record for women aviators.

Urgent Deficiency Bill Largest in Our History

The principal appropriations in the bill, as increased by the Senate, include:

Army	
Supplies	$28,358,000
Transportation	125,000,000
Storage and shipping facilities	150,000,000
Barracks and quarters	67,250,000
Military posts, water and sewer systems	20,180,000
Hospitals	21,270,000
Engineer field operations	70,000,000
Ordnance stores	257,000,000
Ordnance manufacture and purchase	34,000,000
Artillery	114,000,000
Temporary office building	5,775,000
Additional employes	4,470,000
Navy	
Ordnance	10,000,000
Washington gun factory	5,499,000
Yards and docks	6,144,000
Hospital construction	7,750,000
Training camps	12,000,000
Ordnance stations	2,500,000
Miscellaneous	
Fuel and food administrations	1,750,000
War Trade Board	1,018,000
State Department emergencies	300,000
Bureau of Risk Insurance	1,537,000
Enforcement of the espionage act	300,000

U. S. Standardization Board Now in London

The members of the American Standardization Board, who are now in England, were the guests of honor at a reception given by their English colleagues. Among those present were Winston Spencer Churchill, the minister of munitions, and prominent British engineering experts. Speeches were made by Colonel Churchill, F. G. Diffin, and Andrew Weir, and representatives of France and Italy.

Colonel Churchill, in discussing air raids, said that allied superiority in the air is shown by the ease with which allied airmen continually bomb interior German towns in broad daylight, while the Germans only are able with difficulty to reach English and French cities at night.

Mr. Diffin described the present war as one in which 85 per cent, depended upon industrial effort and 15 per cent on military effort. He declared the secret of victory was to combine these two with 100 per cent efficiency.

Los Angeles to Have Government Flying Field

It was announced by Representative Randall of California that he had information from the War Department that a large balloon training station is to be established at Arcadia, about twelve miles east of California on the famous Lucky Baldwin ranch. This ranch comprises 17,000 acres and is widely known in sporting circles by the number of thoroughbred horses from there which have won racing honors.

There has not been any official announcement from the War Department regarding the approval of this field.

School of Aerial Photography Already in Operation

The U. S. Army School of Aerial Photography opened at Kodak Park, Rochester, N. Y., with an enrollment of 560 students. The first week's instruction will consist of military drill and lectures on military matters. Instruction in photography will begin in about two weeks.

Aerial Mail Service Postponed

The aerial mail service which was to be inaugurated on April 15th, has been postponed to May 1st, owing to the delay in the selection of a suitable landing place. It was proposed to use League Island Navy Yard at Philadelphia, but the Post Office Department was recently informed that it would not be available.

The present requirements for a landing place are an area of about 2,000 square feet. The Post Office is working on the development of devices to permit the starting and landing of aeroplanes on a much smaller field. Satisfactory progress is reported.

New Pastime for Allied Flier on Mount Olympus

Eagle hunting is a casual pastime for at least one Allied aviator. Flight Captain Mortureaux of the French Salonica army shot two while flying near Mount Olympus. He landed, secured the game, and returned to his hangar with it.

House Increases Naval Aviation Appropriation

During the consideration of the Naval Appropriation Bill, the House Naval Committee increased the item for naval aviation from $91,000,000 to $188,000,000.

Liberty Motor Production

To Liberty aeroplane motor production will soon be proceeding at a rate of 300 per day from five specially designated automobile and aeroplan factories. The Ford Motor Co. will produce 100 a day, Packard Motor Co., Harmon Co., Lincoln Motors Co. and the General Motors Corp. 50 per day. The greatest production is expected to be attained early this summer, according to "Automotive Industries." The type now being produced in the greatest number is of 12-cylinder type, 450 h.p. developing 1 horsepower to each 2 lbs. of weight.

Wright-Martin to Make Complete Planes

The Wright-Martin Company has been concentrating on an order of Hispano-Suiza motors, and has been turning out 10 per day. It is soon to take up the production of complete aeroplanes. It is understood the company is negotiating for 25 machines to be built at its Pacific Coast plant.

According to "Automotive Industries", 500 of the 150 h. p. Hispano-Suiza motors have been delivered. The Company now working on contract for 3,000 motors of the 300 h. p. type.

Army Spruce Division Ends Competition

Competition between large concerns seeking to supply the Government with aircraft spruce has been eliminated by an agreement reached by representatives of the companies in conference with Colonel Brice P. Disque, commanding the spruce production division of the Signal Corps.

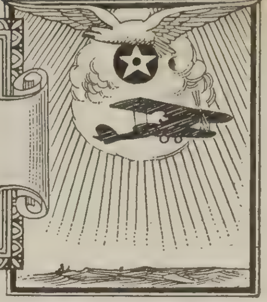
The Aeroplane Spruce & Lumber Co., of Hoquian, has been assigned to Grays Harbor country.

The Warren Spruce Co. of Portland, has been assigned to the Siletz basin and the Alsea bay district and a portion of Grays Harbor Country.

The Grant-Smith-Porter Brothers Co., of Portland has been assigned the Southern portion of Pacific Country and unassigned portions of Oregon.

The keen competition between these three principal companies threatened to result in reduced output, and hence Colonel Disque took steps to end the bitter rivalry.

NAVAL *and* MILITARY AERONAUTICS



Key to Abbreviations

AAD—Assigned to active duty.
ADO—Report to Aviation Supply Depot, Dayton, Ohio.
AGC—Report to Aviation Supply Depot, Garden City, L. I., N. Y.
AHT—Report to Aerial Gunnery School, Houston, Texas.
AMV—Report to Aviation General Supply Depot, Morrison, Va.
APR—Report to School of Aerial Photography, Rochester, N. Y.
BST—Report to Brooks Field, San Antonio, Tex.
CAF—Report to Carlstrom Field, Arcadia, Fla.
CAG—Report to Camp Hancock, Augusta, Ga.
CAP—Commissioned as Captain, Aviation Section, Signal Corps.
CCI—Report to Chanute Field, Champaign, Ill.
CDT—Report to Aviation Concentration Camp, Dallas, Texas.
CGC—Report to Aviation Concentration Camp, Garden City, L. I., N. Y.
CGS—Report to Aviation Concentration Camp, Greenville, S. C.
CLR—Commissioned as Colonel, Aviation Section, Signal Reserve Corps.
CMV—Report to Aviation Concentration Camp, Morrison, Va.
COL—Commissioned as Colonel, Aviation Section, Signal Corps.
CPR—Commissioned as Captain, Aviation Section, Signal Reserve Corps.
CRI—Report to Chanute Field, Rantoul, Ill.
CSO—Report to the Chief Signal Officer, Washington, D. C.
CUI—Report to School of Military Aeronautics, Cornell University, Ithaca, N. Y.
CWT—Report to Call Field, Wichita Falls, Texas
DAF—Report to Door Field, Arcadia, Fla.
DIK—Report to Camp Dick, Dallas, Tex.
DIS—Honorably discharged from service.
EEP—Report to Essington Field, Essington, Pa.
EHT—Report to Ellington Field, Houston, Tex.
ELA—Report to Eberts Field, Loanoke, Ark.
FLR—Commissioned as First Lieutenant, Aviation Section, Signal Reserve Corps.
FLT—Commissioned as First Lieutenant, Aviation Section, Signal Corps.
FOB—Report to Fort Omaha Balloon School, Omaha, Neb.
FRF—On duty requiring regular and frequent aerial flights.
FSO—Report to Fort Sill School for Aerial Observers, Fort Sill, Okla.
GIT—Report to School of Military Aeronautics, Georgia Institute of Technology, Augusta, Ga.
GLC—Report to Gerstner Field, Lake Charles, La.
HHN—Report to Hazelhurst Field, Mineola, L. I., N. Y.
JHU—Report to School of Military Aeronautics, John Hopkins University, Baltimore, Md.
KST—Report to Kelly Field, So. San Antonio, Tex. (When specified in the order, the number of the field is given in parantheses)
LDT—Report to Love Field, Dallas, Tex.
LHV—Report to Langley Field, Hampton, Va.
LTC—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Corps.
LTR—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Reserve Corps.
MAJ—Commissioned as Major, Aviation Section, Signal Corps.
MDO—Report to McCook Field, Dayton, Ohio.
MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MMP—Report to Middletown Aviation Supply Warehouse, Middletown, Pa.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
REL—Relieved from present duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRC—Report to Riverside Field, Riverside, Cal.
RRV—Report to Richmond Aviation School, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
THT—Report to Taliaferro Field, Fort Worth, Texas (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WDO—Report to Wilbur Wright Field, Fairfield, Ohio.

Note 1. Report to Signal Corps troops, Waco, Tex.

Note 2. Report to Camp Funston, Kans., for duty as chaplain.

Note 3. Report to commanding general, Hoboken, N. J.

Note 4. Report to Montgomery, Ala.

Note 5. Report to district manager of inspection, Detroit, Mich.

Note 6. Proceed to New York, N. Y.; Cambridge, Mass.; and San Diego, Cal., for temporary duty, then to Kelly Field, San Antonio.

Note 7. Report to First Lieut. F. G. White, 870 Woodward Ave., Detroit, Mich.

Note 8. Proceed to Boston, Mass., for duty with Board of Officers.

Note 9. On completion of duty, report to Langley Field, Hampton, Va.

Note 10. Proceed to Los Angeles, Cal., then to Sacramento, Cal.

Note 11. Report to Capt. James S. Heaslett, 870 Woodward Ave., Detroit, Mich.

Note 12. Proceed to Long Island City, N. Y.

Note 13. Proceed to Cleveland O., and then to New York, N. Y.

Note 14. Report to Capt. Paul B. Holmes, 870 Woodward Ave., Detroit, Mich.

Note 15. Proceed to Washington, temporary duty, then to Taylor Field, Montgomery, Ala.

Note 16. Report to places named for temporary duty in the order listed.

Note 17. Report to Camp John Wise, San Antonio, Tex.

Note 18. Report to Major Sheppler, 1836 Euclid Ave., Cleveland, O.

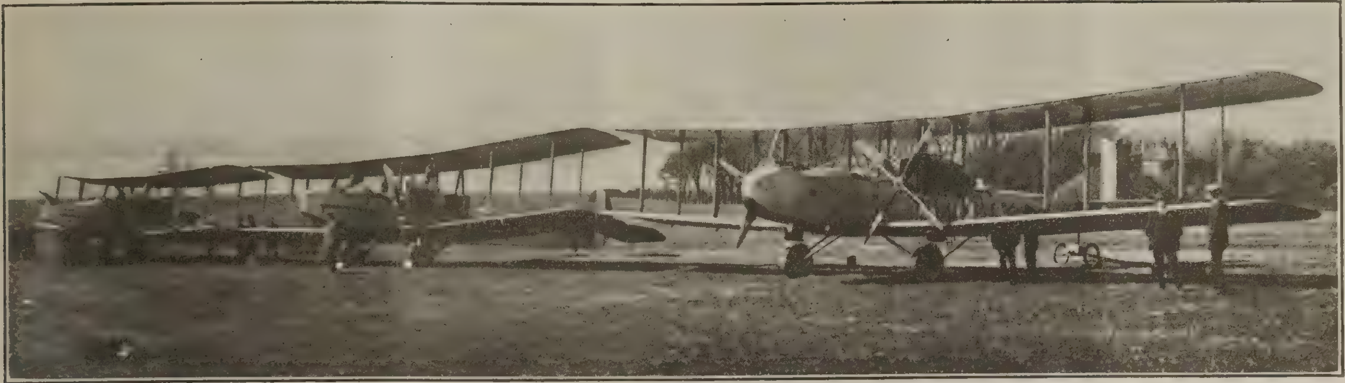
British Official Photo. **A few F.E.2.B machines of the Royal Flying Corps, ready for a flight.**



A group of twin-motored A. V. Roe fighting planes. The machine on the extreme left is equipped with two Sunbeam aero engines, in the centre two Green engines, and on the right two Rolls-Royce engines. Photograph by courtesy of the A. V. Roe Co.. Passed by the British censor.

Official French Aerial Warfare Exhibit Going to Philadelphia and Washington

The official French Aerial Warfare Exhibit, which has had such great success in New York, is going to Philadelphia and Washington. The exhibit includes the 140 remarkable Farré paintings, the official French aerial warfare films and Captain Guynemer's battleplane with which he brought down twelve German aviators. The New York exhibit was a great success. It created substantial interest in aeronautics, the Third Liberty Loan and the war in general. The official and executive committees are as follows:

Committee of Honor: His Excellence, Ambassador Jusserand; André Tardieu, French High Commissioner; Marquis Melchior de Polignac, Major General George O. Squier; Hon. Howard E. Coffin, Chairman, Aircraft Board; Colonel E. A. Deeds, Member, Aircraft Board; Colonel Montgomery, Member, Aircraft Board; Colonel Charles E. Lee, British Royal Flying Corps; Commandant G. Tulasne.

Executive Committee: Mrs. William Astor Chanler, Chairman; Commandant G. Tulasne, Mrs. Edmund L. Baylies, Mrs. John Magee, Mrs. Walter E. Manyard, Mr. Frank Crowninshield, Lieutenant Henri Farré, Mr. Alan R. Hawley, Baron Charles Huard, Mr. Henry Woodhouse, Mr. Walter E. Manyard, Treasurer; Mr. Bennett E. Tousley, Secretary.

The Sky Fighters of France is an exhibition, organized by the French Government and aided in the United States by the Government and by patriotic Americans of all kinds (1) To increase and foster an interest in aeronautics and aircraft production, (2) To support and educate the children of French aviators killed in action.

Chanute Field News

In order to keep the machine shops running smoothly during the flying season, two aerial squadrons, have been designated as school squadrons at this field. One of these squadrons is composed almost exclusively of skilled aeroplane mechanics. Lieut Harry M. Winner has been named as the commanding officer of this squadron.

The first Red Cross nurses arrived at Rantoul this week. Four have been detailed to the local hospital.

The Government is planning the purchase of an auxiliary flying field here. Several sites are under consideration but none have yet been definitely secured.

Personal Paragraphs

Mr. and Mrs. John G. Withrow, of Park Avenue, East Orange, N. J., have announced the engagement of their daughter, Miss Jean Lindsay Withrow, to Flight Commander Oliver Colin Le Boutillier, son of Mr. and Mrs. Oliver Le Boutillier, of Glenwood Avenue, East Orange, N. J. Commander Le Boutillier is in the Royal Naval Air Service, and at present is serving in France. Miss Withrow was graduated from the Dearborn Morgan School in 1916.

Jack Pickford of "movie" fame enlisted in the Aviation Section and is on the way to training camp.

Mr. and Mrs. Aksel Wichfeld, of Washington, who are at the Ritz-Carlton, announced the engagement of Mrs. Wichfeld's stepdaughter, Miss Frances Moore, to Lieut. Henri Marquisan of the French Flying Corps. Lieutenant Marquisan is the son of Henri Marquisan, of Paris, a Chevalier of the Legion of Honor, and is now with the French Aviation Mission in Washington.

Miss Frances Colette Fallon married Lieutenant John B. Golden, of the Aviation Section. The wedding took place in New York. Lieut. Golden was a cadet at the U. S. Military Academy at West Point, but resigned to practice law. He was a member of the Assembly in 1914-1915, and also served as Deputy Attorney General.

When Harold Wright left his mother over a year ago to be a mechanic in the French air forces, he assured her that his duties would never bring him near the enemy. But this was only to re-assure her, for he intended serving as a pilot. It was several months before Mrs. Wright learned the truth—on the occasion her son bagged his first "Boche." He now has two to his credit, as well as an observation balloon.

Mr. J. B. Howell, of the Sales Department of the Bound Brook Oil-less Bearing Company, has been called to active service in the U. S. Army, and is now training at Camp Dix.

Lieut. Georges Flachaire, of the French Army, who is instructing at the Mineola Aviation Field, started on a flight to Washington in a 150 h.p. Spad machine, without making any more preparation than to say to his mechanic, as he started his motor, "I'm off for Washington."

At the American Aviation Training Fields

Lieut. Carroll, the famous composer and librettist in the U. S. Aviation Corps, is recovering from injuries resulting from a bad spill he had at one of the flying fields in Texas. Mr. Carroll is composer of many well-knewn "ragtime" songs, and gave up an income of $30,000 in order to serve in the defense of Democracy.

The course of instruction at the School of Military Aeronautics at the University of California is to be increased to twelve weeks. No definite curriculum can as yet be given out but it is expected that the additional time will be devoted to studies of a purely military character. More emphasis will be put on practical work than on theory and the extra three weeks will give the aviators a much more thorough knowledge of military work.

A school of meterology for aviation students has been established in San Francisco where flying cadets will be able to learn about air pockets, prevalent winds and other things necessary for their training. A. A. Beals, the district forcaster of the Weather Bureau, is in charge of the instruction.

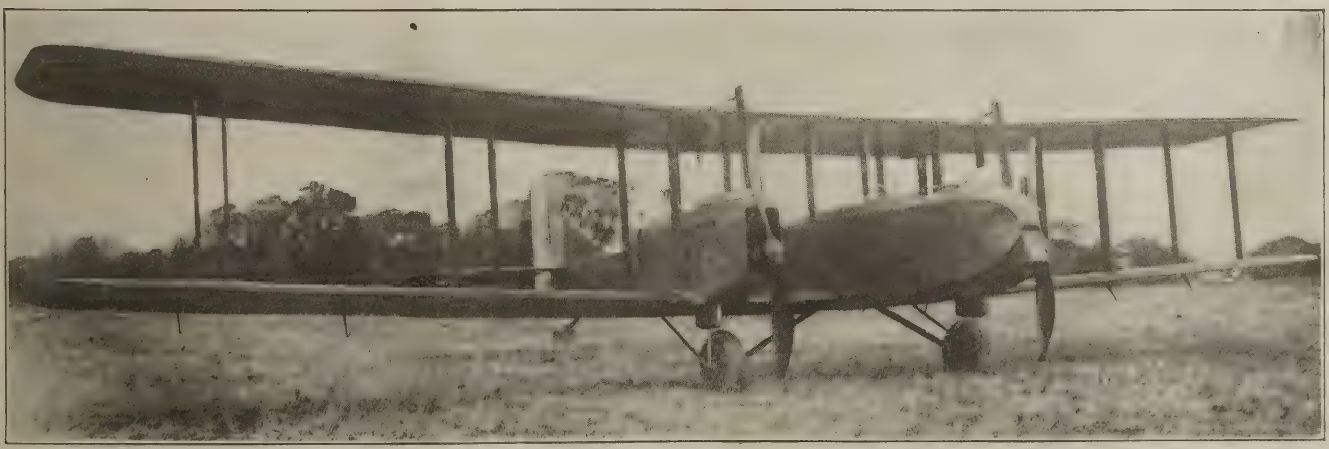
Colonel J. T. Nance, formerly commandant of the cadets at the University of California, has succeeded Colonel H. B. Hersey as head of the Fort Omaha Balloon School.

Major J. P. Mitchel, former mayor of New York City, made his first flight alone recently at Rockwell Field, San Diego. It was so successfully accomplished that he made four more solo flights on the same day, remaining aloft a total of forty-five minutes. Altogether Major Mitchel has only had twelve hours' flying instruction.

Threat of Reprisal Modifies German Policy

It was officially announced that the German Government had released from special imprisonment the British Lieutenants Scholtz and Wookey, the two airmen who some time ago were given prison sentences for distributing propaganda in Germany by dropping printed matter from aeroplanes over German territory.

The release was due to a threat by the British Government to take reprisals unless the airmen ceased to be subjected to unusually harsh treatment.



Three-quarter view of the twin-motored A. V. Roe bombing plane, manufactured by the A. V. Roe Company, of Manchester, England. Photo passed by British Censor.

EVERY MILITARY AVIATOR OUGHT TO KNOW WHAT HIS OWN AND THE ENEMY'S MACHINE CAN DO AND HOW THEY LOOK

By HENRY WOODHOUSE

Author of the "Text-book on Naval Aeronautics", "Text-book on Military Aeronautics", etc.

IN the last number the writer pointed out that the Allied Government found it necessary to teach their aviators and students all about their own machines, and as much as possible about the enemy's machines, particularly their appearance. As a basic principle, the aviator is taught that what does not look like one of the Allied machines must be an enemy machine. Therefore, every effort should be made to bring it down.

The anti-aircraft forces are taught the same thing, and that knowledge of the features of the different types of aeroplanes is one of the prime factors in making the anti-aircraft forces efficient.

Lacking that knowledge, both the Allied air forces as well as the anti-aircraft defenses, get confused and permit the enemy to get temporary advantages, which cost the lives of Allied aviators, as well as of the population of the cities which are raided—without mentioning the strategic advantages which the enemy gains through gathering information or surprising the Allies.

Besides teaching military aviators to know their own and the enemy's machines, what they can do and how they look, the Allied authorities also found it advisable to have continuous progressive changes in their types of aeroplanes.

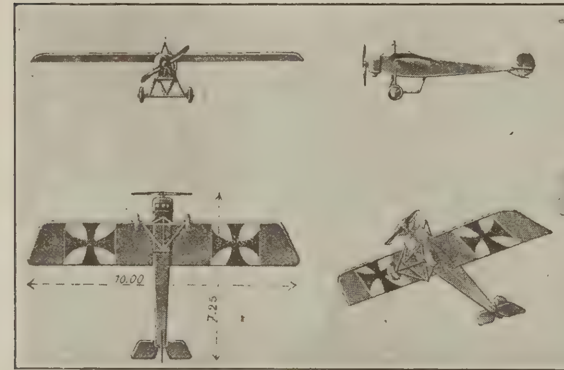
It was found that German aviators had a certain amount of fear for a new type of aeroplane, because they did not know what it could do and past experience had taught them to beware of appearances. As a member of the Lafayette Escadrille put it: "The Boche was never so surprised as when he attacked a certain type of machine which looked like a two-seater, and got fired on by the third passenger, who was an extra gunner, well equipped with twin Lewises."

The policy of keeping the enemy "guessing" is good strategy—so long as it does not interfere seriously with production. It can be applied especially in the smaller types of machines used to maintain the supremacy in the air during the daytime on the fronts. It has little value in so far as the large bombing machines used for night bombing are concerned, because the night aeroplanes cannot be seen. It may be deducted from the types of German machines captured that the Germans are also following this policy. They keep up a continuous progressive change of types, adopting the good points of captured Allied machines, adding other points which are suggested by the progress of the science.

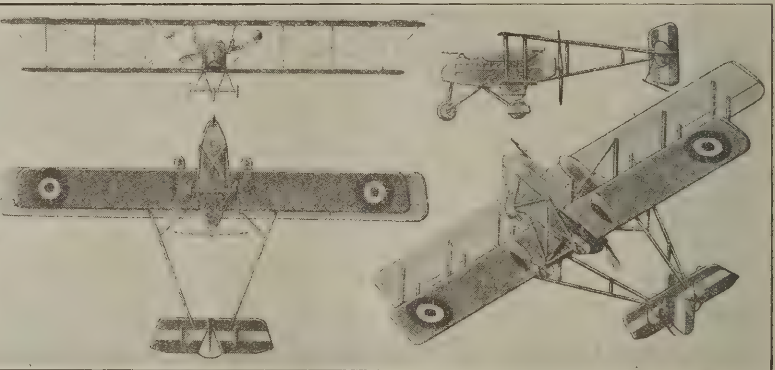
The Gothas followed the capture of the Handley-Page bomber, and now the dispatches advise that the Germans are building larger machines equipped with four motors.

Some of the smaller machines look very much like the French and British machines and it would be hard to recognize one from the other, were it not for the iron cross on the planes. This similarity in characteristics has necessitated closer study of German types and how they look.

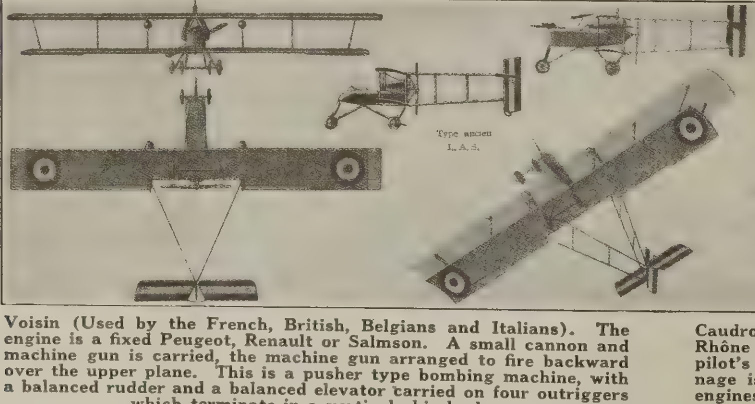
Aeroplanes to follow in succeeding issues, in connection with the identifications of military aeroplanes: Handley-Page, Pomilio, Avro, S. V. A. and others.



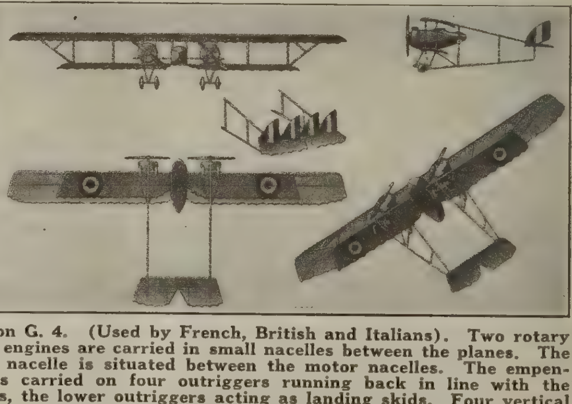
Fokker monoplane (German). Follows closely the French Morane, especially as to its balanced elevators. Equipped with a rotary Oberursel 80 or 100 H.P. engine. One of the first German machines to successfully employ a mechanically operated machine gun firing through the sweep of the propeller



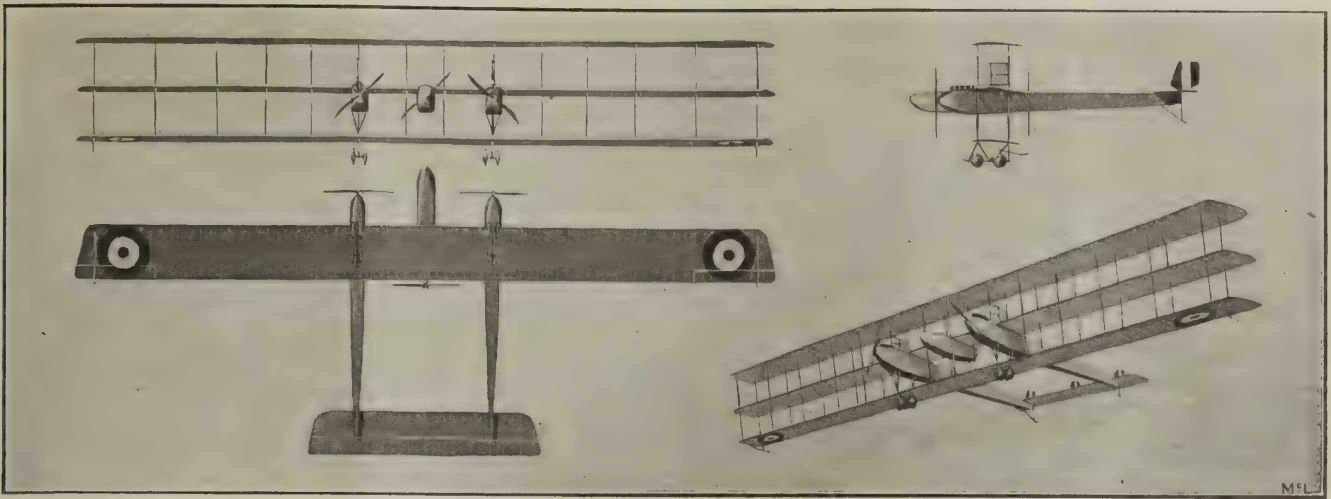
Bréguet (French). Bombing machine of the pusher type. Renault engine. Carries a light cannon or machine gun. Landing gear, 3 wheels. Two vertical fins and a vertical rudder. The Bréguet has been used in numerous raiding expeditions, an operation for which it is particularly fitted



Voisin (Used by the French, British, Belgians and Italians). The engine is a fixed Peugeot, Renault or Salmson. A small cannon and machine gun is carried, the machine gun arranged to fire backward over the upper plane. This is a pusher type bombing machine, with a balanced rudder and a balanced elevator carried on four outriggers which terminate in a vertical chisel edge



Caudron G. 4. (Used by French, British and Italians). Two rotary Rhône engines are carried in small nacelles between the planes. The pilot's nacelle is situated between the motor nacelles. The empennage is carried on four outriggers running back in line with the engines, the lower outriggers acting as landing skids. Four vertical fins and four rudders are located above the tail



Caproni Triplane (Italian). Italy's best known aeroplane, and the [illegible] engines; two located in tractor position at the front end of each fuselage, and one pusher at the rear of the pilot's nacelle at the center. Capable of carrying great weights (nearly 3000 lbs.), and used particularly in bombing work. The design is distinct and easily distinguishable by its three main planes, two tractor fuselages and central nacelle, the monoplane tail with a single tail flap (elevator) and three balanced rudders situated above the tail. The landing gear is composed of four pairs of wheels located below either fuselage

War Department Acts on Aerial Coast Defense

Active preparations to strengthen the aerial defenses of the Atlantic seaboard were begun by the War Department, with the appointment of an army board to select sites for aero squadrons and balloon companies.

Major Norman W. Peek, of the Signal Corps, was named to head a board to meet at Charleston, S. C.; Fort Totten, N. Y., and Boston. Commanders of the South Atlantic, Middle Atlantic and North Atlantic Coast Artillery districts will each name an officer to sit with the board, while it is considering needs of each district.

The other members of the board are Major Edward D. Sinks, Medical Reserve Corps; Second Lieutenant C. L. Stuckland, Mr. W. P. Stevens, A. M. E. Signal Corps at large, and a fifth member to be selected by the commanding officer of each coast artillery district upon the request of the senior member of the board.

Army Balloonists Injured

Nine army aeronauts were injured when the balloon in which they were making a trial flight from San Antonio fell 3,200 feet near Killeen, Texas.

Captain B. H. Fournier, of San Antonio, suffered a severe scalp wound; Cadet G. W. Adams, a broken leg, and Cadet E. M. Hawley's back was sprained.

Something went wrong with the valve in the top of the gas bag, it was said, when the balloonists attempted a landing. The balloon dropped at a speed of thirty feet a second. All the injured were taken to San Antonio.

N. Y. University to Assist Aircraft Program

New York University soon will begin vocational training of 100 soldiers of the National Army for service with the United States aeroplane forces in France, according to an announcement made by Dean Charles Snow, of the Engineering School, at University Heights.

The university's engineering school, its faculty and its equipment are to be placed at the War Department's disposal for the instruction of the soldiers in various mechanical lines related to aeroplane service. The instruction will be under the general supervision of any army officer.

The War Department has telegraphed to the university that the soldiers would be assigned to the Engineering School for instruction beginning April 1. The course will last until October.

Twenty of the soldiers will be trained for service as gas engineers, twenty as mechanics, thirty as electricians and twenty will receive special instruction in the delicate wood working required in keeping the aeroplanes in working order.

This co-operation by the university with the War Department in the rapid training of soldiers for the aeroplane service in France is understood to be the first step in a programme of extensive co-ordinated effort by the institution with the military authorities in making skilled technical and mechanical experts available for war work.

Army Insurance Totals Twelve Billion

More than $12,000,000,000 worth of insurance has been written on the lives of American soldiers, sailors and nurses by the War Risk Insurance Bureau, Secretary McAdoo has announced today. Up to the close of business March 6, 1,392,324 applications, representing insurance of $11,256,448,500, had already been received at the bureau, and late reports from the American forces in France, together with insurance now in transit from distant points, indicate that the total written to date is well above $12,000,000,000, covering more than 1,500,000 persons in the military or naval service. In February alone more than $5,000,000,000 worth was written.

The average amount of insurance applied for is $8,095. The maximum permitted is $10,000 and the minimum $1,000. Final figures show that the United States Army, both here and abroad, is well above 90 per cent. insured.

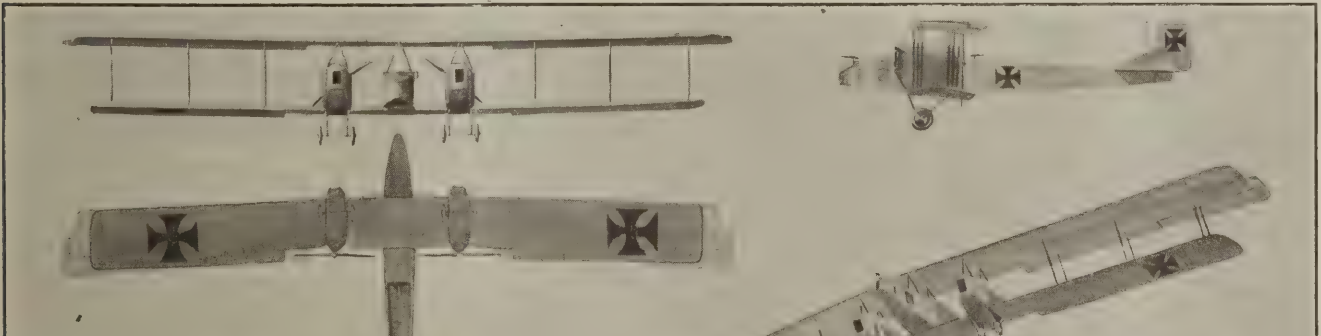
Commission on Naval Bases Recommends Establishment of Naval Air Stations

In a preliminary report by the Commission on Navy Yards and Naval Bases it is recommended that coastal air stations be established at Brunswick, Ga., at Tampa on St. Andrew's Bar, and Mobile, Ala. If necessary, the report states a station can be established at Sabine Pass, Texas, though it is not recommended as a good site for the purpose.

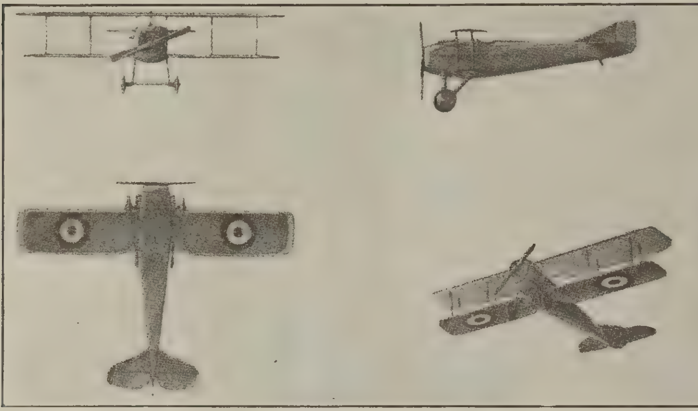
On the Pacific coast a main aviation station at San Diego, a base aviation station at Puget Sound and Mare Island Navy Yards and an operating aviation station at Port Angeles, Wash., are also proposed.

Aviation Officers Visit Y. M. C. A. School

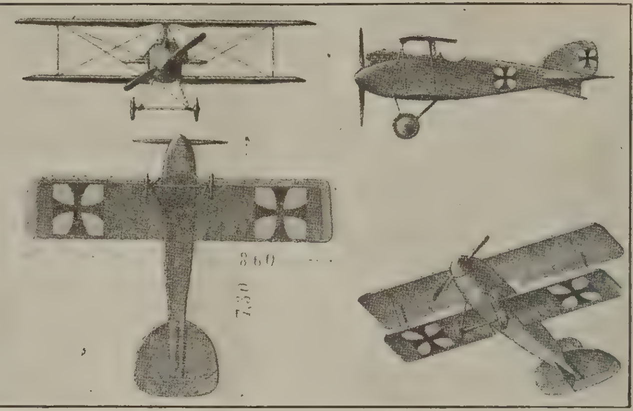
During the past few days a group of officers in the U. S. A. Aviation Service have been the guests of the Aeroplane Mechanics School of the West Side Y. M. C. A., while putting the finishing touches on their education in the mechanics of certain types of engines, notably the Gnome, with which all the Government schools are not equipped. The visit of the officers was arranged through Benjamin Williams, secretary of the Manufacturers' Aircraft Association, by request of the Government Aviation officials. They are all here enroute for the front and expect to sail shortly for "Somewhere in France."



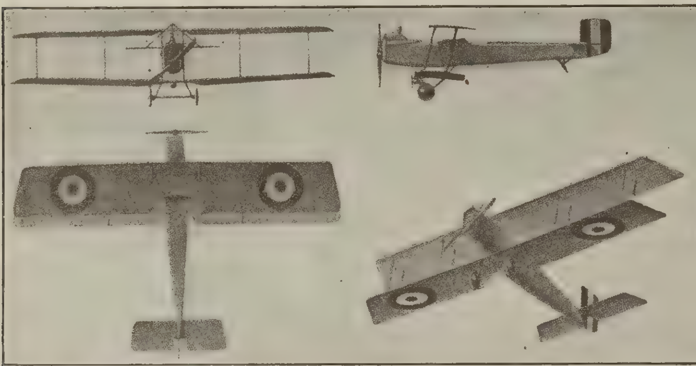
Gotha (German) twin-engine warplane. The machine used in a considerable number of raids on London and recently on Paris. Has a span of 78 feet and carries two Benz engines totalling to 450 in H.P. The machine bears a resemblance to the British Handly-Page, from which data for constructing the Gotha was obtained, but it is a pusher and the Handley-Page a tractor. Identified by its overhanging balanced ailerons (similar to the Handley-Page) and its usual monoplane tail (differing from the British machine which has a biplane tail). Three machine guns are carried; one in the front, one at the rear cockpit and a third below it, which can be fired downward and backward through a so-called "gun-tunnel" on the underside of the fuselage.



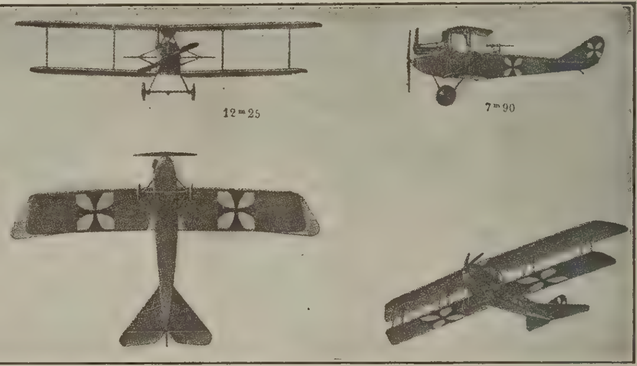
Spad single-seater scout. (Société pour l'Aviation et ses Dérivés). Used by the French and British. All Spads are equipped with Hispano-Suiza engines, either 150 or 200 H.P. This machine is easily confused with the Albatros, a German scout. One of the most popular scouts of all the French or British machines, and therefore used in large numbers



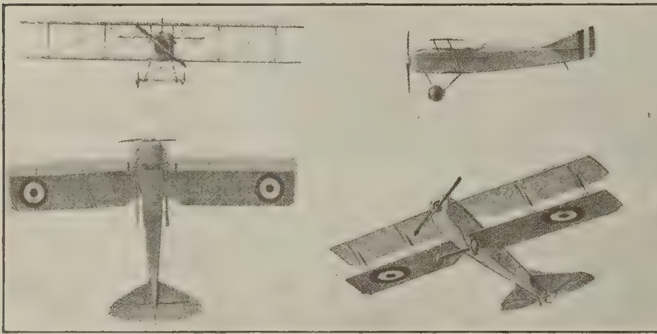
Albatros D. 1. Single seater scout. (German.) One of the fastest of German aeroplanes. It is equipped with a 170 H.P. Mercedes engine or a 225 H.P. Benz and provided with two fixed machine guns arranged to fire through the propeller. The propeller is capped with a forward spinner which carries out the streamline effect of the body



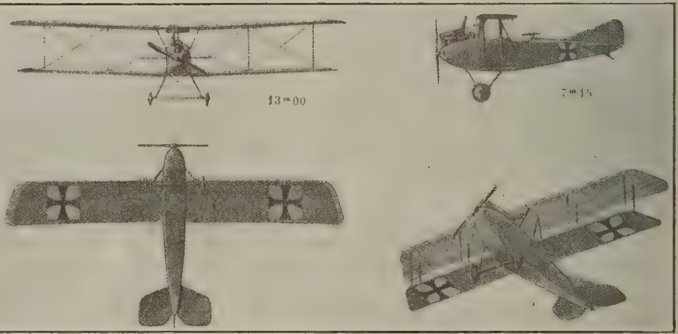
A.R. or A.L.D. (Type Corps d'Armée, with a Renault or Lorraine-Dietrich engine.) French machine for all uses. The A.R. has a Renault engine and the A.L.D. has a Lorraine-Dietrich, with a fixed machine gun firing through the radiator and one movable at the rear. Planes are invertly staggered and the fusilage is set above the lower plane



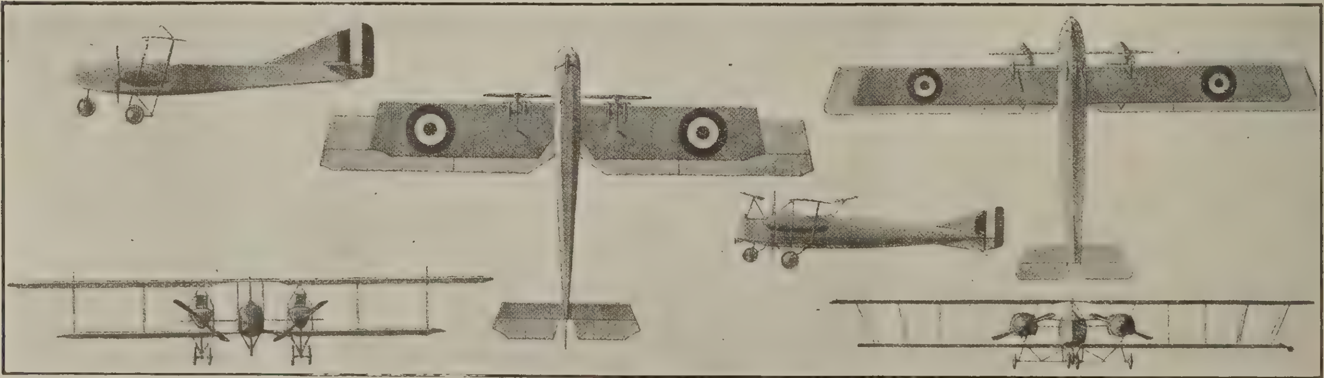
Rumpler. (German.) Has the Mercedes 175 H.P. engine, a fixed and a movable gun. Radiator semi-circular, set into the upper plane. Vertical exhaust stack for the engine. Carries lance-bombs at times. San, 12m25. Length overall, 7m90. Later Rumplers are equipped with 260 H.P. Mercedes or a 250 H.P. Mayback engine



Spad two seater. (French.) Hispano-Suiza engine. Similar in outline (and construction) to the Spad scout. The two-seater carries a movable gun at the rear, in addition to a fixed Vickers machine gun synchronized with the propeller and firing directly ahead. The planes are staggered and swept back at about 3°



A. E. G. (Allgemeine Elektrizitäts Gesellschaft.) A German two-seater with a 175 H.P. Mercedes engine. It carries a gun synchronized with the propeller and one movable at the rear. Upper central wing panel flat in span; outer sections with slight dehedral. Radiator carried in the central panel and a stack leads the exhaust of the engine above the plane. Planes slightly swept back



Letord. (French.) A three-plane twin-motored biplane tractor using Hispano-Suiza engines. The planes are staggered backward and the struts are run vertically backward at the tops. Five wheels are used in the landing gear

Morane-Saulnier twin-motored. (French.) This is a three-place tractor with nacelles carrying either rotary Rhone engines or fixed Hispano-Suiza engines. Two machine guns are used. Besides the struts at the body and nacelles, there are two pairs of vertical struts and two pairs of inclined struts at either side of the body. Features of this machine have been copied by the German A.E.G. and the Gotha

METEOROLOGY: AIR CURRENTS AND EDDIES

By PROFESSOR W. C. DUFFIELD, D.Sc.

THE eastern coast is generally under the influence of a stream of air which flows in from the Atlantic Ocean from the west or southwest. Unlike the trade winds, which are the feature of the latitudes nearer the equator, and which blow steadily and regularly, this current is broken up into eddies. These disturbances are carried along by the stream, but they also move through it and stir up different masses of air as they pass along.

These eddies prevent the winds from blowing perpetually from the southwest, and they provide the succession of winds which is experienced by the country over which they travel. We may represent their behavior by Fig. 1, in which the general flow of air is indicated by the straight arrows flying from a southwesterly direction, and a typical eddy by the curved arrow. As this particular eddy moves along, the country below is subject first of all to a south wind blowing in the advance part of the eddy, and after a succession of winds in other directions to a wind from a northerly direction, shown by the arrow in the rear of the eddy. It is these eddies which form in the stream of air flowing over the country which are responsible for the variable winds experienced in these latitudes.

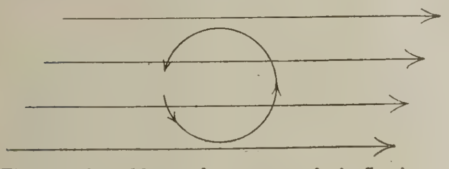


Fig. 1.—An eddy in the stream of air flowing from the Atlantic

The Flow of Air

The stream is never free from them and often there are several eddies over different parts of the continent at the same time, and the flow of air over those parts of the country which lie between them is apt to present a very complicated problem; long experience has, however, enabled meteorologists to learn how the winds are likely to blow for any given distribution of these eddies, and it so happens that the air currents which are set up when a single eddy is passing over the country are of great importance in aviation, and are simple to understand. Good flying weather and bad flying weather are determined by the kind of eddy and by its exact position with regard to the place on the earth's surface over which the airman is flying. We shall first discuss the nature of the eddies which an aeroplane is likely to experience, with special reference to the currents of air composing them; this involves one feature which is not quite what would have been expected, and therefore requires some explanation; we shall later on explain how it is possible for the airman to discover by means of a weather map the existence of these eddies and to recognize them and to gain an idea of the kind of weather they are likely to bring with them.

It must be realized that meteorology can never be regarded as an exact science, and that on any particular occasion there may be conditions of temperature or some local influence which will interfere with the general nature of the disturbance. All that we can hope to do is to give the broad basis upon which the actual weather conditions are founded; the possibility of their being modified must not be overlooked.

An eddy such as is pictured in Fig. 1 represents a typical cyclonic disturbance or "depression." The circulation of air is seen to be anti-clockwise, but it is only developed in this form in the strata which are at least two or three thousand feet above the earth's surface. Nearer the ground the friction of the air causes the direction of the air currents to take a turn inwards towards the center.

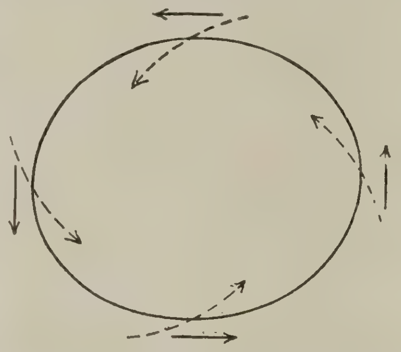

Fig. 2.—The flow of air in the upper levels of the atmosphere is represented by the full arrows; the flow near the ground, by the dotted arrows. The diagram represents the circulation of air about an eddy.

Rotation of the Earth

The directions of the air flow at ground level and at high altitudes are shown in Fig. 2. The full arrows represent the direction of the wind at high levels, the dotted arrows the direction at ground levels. An airman rising into the air will consequently experience a change of wind which will materially affect his course. It is scarcely necessary to remark that in order to maintain an inward flow of air towards the center the atmospheric pressure must be lower there than in the surrounding country; that is to say, the system is typical of a low barometer. The fact that an area over which the pressure is low can exist without a direct flow of air into it is in itself remarkable. One would expect the air outside, which is at a higher pressure, to pour straight into it and make up the pressure to its normal value, but this is not the case; it could only be so if the earth ceased to rotate. The rotation of the earth is responsible for deflecting the stream of air, which undoubtedly tends to flow directly into the low pressure region, and causing it to take a curved path.

In the northern hemisphere the rotation causes every current of air to be deflected to the right of the direction in which pressure would tend to drive it. If, for example, in Fig. 3, L is a part of the country over which the pressure is abnormally low, a mass of air at A some distance from L would be under the influence of a force tending to drive it from A into L, because of course the air, like any other fluid, tends to be driven from a place where the pressure is high to a place where it is low. But instead of moving along the path A, L, the rotation of the earth causes it to deviate to the right—that is to say, along A, B. At B the tendency is for it to flow directly along B, L, but again the influence of the rotation is to deflect it along B, C, instead. From C it moves to D and so on. The direction of the currents of air at any moment is therefore given by the curve A, B, C, D, E, F. This is perhaps the most difficult feature of meteorology, and one which has made it an unpopular science, but once the fact is grasped that air does not flow solely under the influence of the pressure distribution, but also under the influence of the rotation of the earth, the main difficulty is overcome, and the rest is comparatively plain sailing. The reader will probably have realized that it is not always quite clear whether the pressure differences are the cause of winds, or whether the winds occasion the differences of pressure. What we do know is that they are intimately connected, and that the greater the differences of pressure between different parts of the country, the greater the strength of the winds. When the barometer is falling rapidly as a disturbance passes over the observer, the winds are likely to be of greater force than when the fall is gradual.

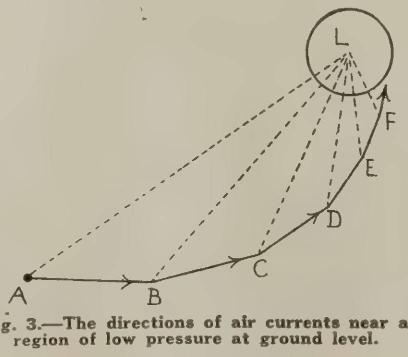

Fig. 3.—The directions of air currents near a region of low pressure at ground level.

The whole phenomenon of the flow of air about a region of low pressure is rather like the flow of water near a hole in a bath, though the two are by no means the same in structure. The water does not flow straight into the hole, but circles round it, more or less spirally, the currents at the bottom being more disturbed by friction than those at the top.

Eddy Circulation

It is a very curious thing that the air in eddying round a low pressure area never actually seems to get to the center. It used to be thought that the air eventually arrived there and then flowed upwards, very much as if it were going up a vast chimney; indeed, the idea of an upward current in the center was regarded as essential for the maintenance of this type of whirl in the atmosphere, but the investigations of Mr. Dines in this country have shown that there is practically no updraught in the center of the eddy and that the old idea did not seem to be satisfactory. Sir Napier Shaw and Mr. Lempfert have recently succeeded in tracing the path of a mass of air in the neighborhood of a depression, and they find that the air does not as a rule succeed in flowing into the center at all; there is always a flow directed spirally towards the center at ground level, as we have already seen, but as the center is moving away towards the northeast it has left the place towards which the flow was directed before the streams get there.

The particular type of disturbance with which we have been dealing represents a region in which flying is as a rule attended with a certain amount of risk; it is usually cloudy, windy and rainy, and a type of squall sometimes accompanies it which makes flying impossible. This eddy circulation is usually termed a "depression" or a "low," and is frequently a visitor to these shores; it usually extends over an area very much larger than the British Isles.

When the eddy goes round in the other direction—that is to say, in a clockwise sense in the northern hemisphere—the weather is usually favorable for flight, the barometer then stands high in the center, and the air tends to stream outwards instead of inwards, and the disturbance is known as an anti-cyclone.

WING BRACING AND HEAD RESISTANCE

By MARCO POLO

IN COMPARING the performances of modern aeroplanes with those of pre-war days, one cannot but be impressed by the enormous progress made during the few intervening years. This progress has not been in one direction only, but is distinctly noticeable in every aspect of the capabilities of an aeroplane, such as climb, manœuverability, reliability, duration and speed To what can this great improvement be ascribed? Not to any single thing by itself, but to general improvement in detail design. As far as the speed and climb are concerned, progress has been to a very large extent due to engines of greater reliability and higher power. It is doubtful, however, whether this increased power is the sole, or even the chief, cause of the progress made. Very great improvements have been made in the aeroplanes themselves, notably as regards wing sections, of which there are now in existence examples far exceeding in efficiency those available before the war. Another point that has received the closest attention of designers and constructors is the reduction of head resistance. This applies not only to the body of the aeroplane, but also to the wing bracing and strutting; and it is the latter aspect with which it is intended to deal in the present notes.

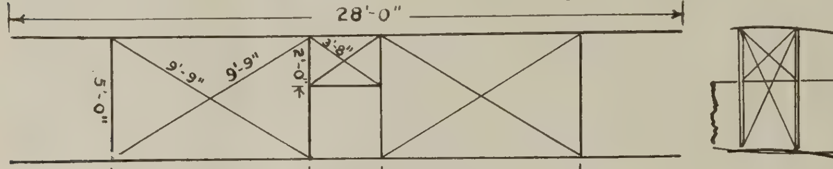

Fig. 1. Diagram of the Wing Bracing of a Standard Scout.

Span, upper and lower, 28′ 0″; chord, 5′ 0″; area, upper, 140 sq. ft.; lower, 125 sq. ft.; total, 265 sq. ft.; gap, 5′ 0″; total length of struts, 28′ 0″; wires, 128′ 0″; resistance factor, 184.

In order to provide a foundation on which to base a comparison of various forms of wing bracing, it will be assumed that a designer is faced with the problem of designing a machine to fulfill certain given conditions, and that in order to do this he finds that, with the power and wing sections at his disposal, he requires an area of 265 square feet. This is, perhaps, a somewhat larger area than that used on the latest fighting machines, but as this fact will not affect the argument qualitatively, it has been chosen for the sake of convenience. Now, in order to get the best possible results out of his machine, with the area, wing section and power given, assuming that the form of body has already been decided upon, the designer will naturally ask himself what is the form of wing bracing that will give the least resistance, conforming, of course, with the question of proper structural strength.

In Fig. 1 is shown diagrammatically the front spars with their wire bracing of what may be termed a standard scouting biplane The span is 28 ft., and the chored and gap are 5 ft. respectively. Although a stagger is almost universally employed in modern scouts, we have chosen the vertical type as being simpler to deal with, and as this does not materially affect our argument, it is, we think, permissible. The "free length" of spar is about 8 ft. 3 ins., a somewhat excessive distance for great strength, and calling for a fair size spar, but the proportions, if not the actual dimensions, conform approximately to standard practice. The attachment of the top plane is of the type termed "canopy" mounting by the Germans, *i. e.*, there is a short top plane centre section, supported on four vertical struts from the body.

From the list of dimensions accompanying each diagram, it will be seen that the last figure in the list is called "resistance factor." This expression, which is employed for want of a better term, had better be explained before proceeding any farther. Before it is possible to make a fair comparison between the various forms of wing bracing in a machine of the scout type, it is necessary to assign to each of the component parts of that bracing a value for resistance. Now, as the purpose of the present notes is not to go into calculations of the actual resistance in pounds at a certain speed, but merely to compare one form of wing bracing with another, it will not be necessary, for the purposes of the argument, to know the actual resistance per foot run of the wires and struts employed, but it *will* be required to know how the resistance of one unit length of strut compares with that of one unit length of wire.

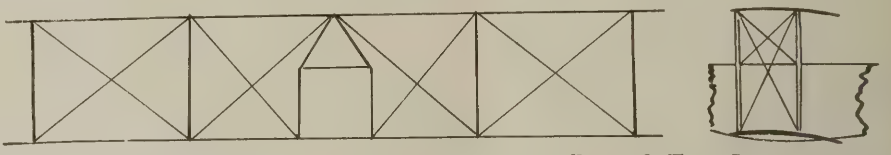

Fig. 2. Diagram of the Wing Bracing of a Halberstadt Type Scout.

Span, upper and lower, 28′ 0″; chord, 5′ 0″; area, upper, 140 sq. ft.; lower, 125 sq. ft.; total 265 sq. ft.; gap, 5′ 0″; total length of struts, 50′ 0″; wires, 183′ 0″; resistance factor, 283.

From the reports published by the various institutions carrying out wind-tunnel experiments, it would appear that a 10-gauge smooth round wire offers approximately the same resistance per foot run as a good section strut of the dimensions employed on a machine of the scout size and type. Since, however, in modern aeroplanes, at any rate on high speed ones, round wires are never employed, it will not be fair to assign to the struts the same resistance value as that of the wires. The so-called "streamline" R. A. F. wire, which is not, of course, a true streamline section, is not generally favored by private designers for various reasons, so I shall refrain from making the comparison with this particular type of wire. A method more generally preferred by many is to employ duplicate cables placed at a distance of about an inch behind one another and having a wood-filling in between them. Although this combination may not give an absolutely true streamline section, its resistance is in all probability quite as small as that of an R. A. F. wire, and it will, one is inclined to think, be found to be considerably stronger, especially against sudden loads, such as those imposed on the cables when flying in a "bumpy" wind. If it be assumed that such a combination of cables and wood-fillings will measure ½ in. by 1½ in., while the strut sections measure 1¼ in. by 4 ins., we shall take it, in view of the less perfect section of the cables *cum* wood fairings, that the resistance per foot run of the struts will be twice that of the cables. This figure is, admittedly, quite an arbitrary one, and as the whole argument rests entirely upon these relative resistance values, it is, of course, important that they should be correct. I do not think, however, that they will be found to be very far wrong. Data relating to this subject should be available in every designing office, and thus designers should be able to check the accuracy of our assumption. In any case, any error due to incorrectness of this so-called resistance factor will only affect the argument quantitatively.

Referring again to Fig. 1, it will be seen that the "resistance factor" of the standard scout for the area and proportions chosen is 184. This figure is arrived at by multiplying the length of struts by two, the value assigned to strut resistance compared with that of the cables, and adding the product to the total length of wires, or, more correctly speaking, cables. This "resistance factor," then, forms a basis for comparison.

In Fig 2 is shown the form of bracing employed on the German Halberstadt biplanes, *i. e.*, there are two pairs of inter-plane struts on each side, and the top planes are attached to *a cabane* instead of to the "canopy" usually found on scouts of British design. Next let us examine how this form of bracing compares with that shown in Fig. 1. The area, as before, is 265 sq. ft. The total length of wires is found to be 183 ft. against the 128 ft. of the standard scout type of Fig 1. The total length of struts is 50 ft. instead of the 28 ft. found for the standard scout. The "resistance factor," therefore, is 283 against 184, quite an appreciable difference, which would reduce considerably the performance, both as regards speed and climb, of the machine with the Halberstadt type bracing. It should be pointed out, however, that this bracing would be very much stronger, as the "free length" of spar is considerably shorter than with the one pair of struts arrangement. The reason for its adoption in the Halberstadt is to be sought for in the fact that a large heavy water-cooled engine was fitted, whereas most, or at any rate many, of our small scouts have a much lighter rotary engine. For a light engine the Halberstadt bracing is, therefore, to be considered less efficient than the standard scout bracing.

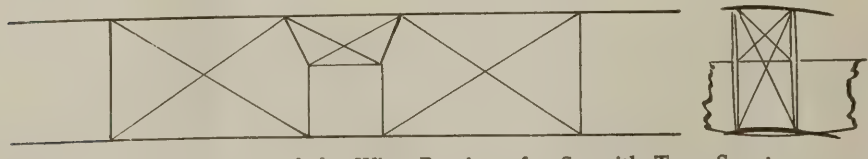

Fig. 3. Diagram of the Wing Bracing of a Sopwith Type Scout.

Span, upper and lower, 28′ 0″; chord, 5′ 0″; area, upper, 140 sq. ft.; lower, 125 sq. ft.; total 265 sq. ft.; gap, 5′ 0″; total length of struts, 29′ 0″; wires, 128′ 0″; resistance factor, 186.

The first development of what is termed in this article the standard scout bracing is shown in Fig. 3, which is that first introduced by the Sopwith Aviation Co., and since employed by many others. This arrangement differs from the standard only in the placing of the body struts supporting the centre section of the top plane. These struts, it will be seen, instead of forming a vertical continuation of the body struts proper slope outwards a few degrees. An examination of the list of dimensions underneath the diagram in Fig. 3 shows that the total length of wires is the same as that of Fig. 1, while, owing to the outward slope of the struts, the total length of struts is one foot greater than that of Fig. 1. The "resistance factor" is therefore 186 against 184 of the standard scout, a negligible difference when it is remembered that by having the struts sloping outwards the "free length" of the upper spar, which is the heavier loaded, is reduced, with a consequent strengthening very desirable in a machine of this type. This arrangement may then be said to be very good, both as regards resistance and strength.

SPINNING

By DEAN I. LAMB

SPINNING arises from sideslipping. Sideslipping is of two kinds—outwards and inwards. A flyer must get to know which of these his sideslip is, and whether his air speed is normal or abnormally low. The former (outwards sideslip) is almost always known when it is possible for the flyer to be aware that he is turning—when he is not in a cloud.

The air speed can only be known with any assurance from the air-speed indicator, and no amount of experience can do more than approximate to this if there is any wind blowing, though a skilled pilot gets some idea of his speed being adequate by reason of the resistance he feels to the moving of his controls. For this he must, of course, be acquainted with the particular type of machine he is flying. Opinions differ as to the value of relying on the air speed indicator as against going by "feel," but from past experience and observation I think that the instrumental method is the better and safer, provided a reliable instrument is used and kept in order. The instrumental method is used to the exclusion of "feel" in all European countries.

Always, when the aeroplane gets out of control, the engine should immediately be throttled down or switched off. If at a reasonable altitude the aeroplane should be dived, but if there is no room for a dive there will probably be a smash in any case; it is accordingly better that the throttle is closed and switch "off" so that any danger of fire is avoided.

The problem is best considered separately on the unstable and the stable aeroplane.

Unstable Aeroplane With Speed Correct

The only way a spin can occur with the aeroplane at its correct speed (or higher speeds) is by the fin surface aft being too small or incorrectly disposed—one kind of instability in the aeroplane. Given the proper speed; whether the sideslip causing the spin is outwards or inwards, the inadequate fin area aft is the cause of the spin. The fin area is a matter of design, and the flyer's best course of action is advised in the treatment below; but in any case he can increase the effective fin surface aft by holding his rudder appropriately. When in a left-hand spin hold rudder to right or in R. H. spin hold rudder to left. Usually, when a flyer goes into an unexpected spin he is a bit confused, so it is advisable to make it a general rule to hold the rudder in the straight position.

Stable Aeroplane With Speed Correct

If the flying speed is correct and the aeroplane stable, sideslips correct themselves. This does not imply that foolhardy over-banking which produces the sideslips is allowable. Thus, if a sideslip be obtained by heavy banking without much turning, this means that the aeroplane, under gravity, sideslips towards the ground, and therefore the side wind comes on the flyer and on to the aeroplane in a direction upwards from the ground. This resultant "upwind" will be strong when the slipping is severe, and so the aeroplane will tend rapidly and strong to re-align itself into this side wind, thus overcoming the sideslip if there is space enough. Nevertheless, two things are to be noted in this connection:

(1) The rapid re-aligning of the aeroplane into the new direction will appear like the beginning of a spin, though it really need not be a spin; and—

(2) The flight path will be directed downwards, since the wind came upwards from the earth, and such a flight path is, of course, dangerous if so near the ground that there is not time enough to flatten out. Such a movement is not to be described as a spin, because the rotation is not continuous and ceases automatically when re-alignment to the relative wind has been achieved.

Unstable Aeroplane With Speed Too Slow

Six conditions may occur in various unstable aeroplanes:

(1) The fin surface aft may be inadequate minus above.

(2) The fine surface plus rudder may be inadequate.

(3) The rudder reaction may be too strong for the pilot to master.

(4) At very slow speeds the operation of the ailerons may produce spinning tendencies which the fin and rudder, though otherwise adequate, cannot counter.

(5) The fin surface may be too unsymmetrical above and below the body.

(6) The total fin surface aft (fin plus rudder) may be too great.

I will take all these cases and first consider sideslips outwards. In No. 1 the only general direction that can be given is that the rudder should be held straight and the aeroplane dived for speed recovery. (If the spin is so rapid that the angle of attitude of the rudder to the air approaching it is greater than 15 degrees, it would as a general rule be best to hold the rudder straight. It would seem that if the spin is caught before it has developed any great rapidity, the rudder may be turned in the direction which checks the spin and then straightened. As a rule the rudder should not be turned very much, and so for simplicity it is advisable to stick to the rule, "Keep the rudder firmly straight.")

In No. 2 the general instructions to the pilot are the same as in No. 1.

In No. 3 the general instructions to the pilot are that he must maintain the full pressure that he can exert toward keeping the rudder straight.

No. 4 is more complicated; the occasion when a spin can arise is when a turn is being made without enough bank, presumably because the aeroplane is so near the ground that there is danger of touching the ground with the lower wing tip, or else by reason of inexperience. Apart from any warping effect by the pilot, the mere fact that there is a spin, by giving the outer wing the greater speed, tends to lift it; this is supposed in the present case to be opposed by the pilot, who is for some reason trying to avoid a bank. This opposition is expressed by his pulling the inner aeleron down. If on this occasion the speed is too low (contrary to the effect at normal speeds) it *diminishes* the lift of the inner wing top and also adds largely to its resistance. Accordingly this wing is retarded and drops still more, much to the pilot's surprise, unless he has had lots of experience.

This has two effects: It tends to give the aeroplane its proper bank, but it also causes a rapid spin round the retarded wing tip. This type of spin persists, and as the bank increases the spin round the lower wing tip amounts to a nose dive, which itself would cure the loss of speed and so make all safe if there were enough ground clearance.

The general instruction to a pilot whose speed is at the stalling point is, therefore, to turn the outer aeleron down hard. This will retard the spin, and, if the aeroplane is really at the stalling point, will avoid banking the aeroplane. This may be easier expressed in another way by saying that the aeleron control effects are reversed at stalling speed.

(This is what should be done to remedy a spin, but the correct thing is really *NOT to let the speed get too low.*)

But, to continue, as soon as the aeroplane is straightened by this inverted action in the aeleron controls the engine should be opened full, trusting that the machine will pick up enough speed not to "pancake" too hard. This situation is in any case a bad one, and no pilot should attempt an under-banked turn with the aeroplane flying near its stalling speed.

Unluckily, this particular form of error is one which there are special excuses for falling into, and it occurs quite frequently, sometimes with fatal results. Thus, if the aeroplane is over ground that is too rough for landing and the engine cuts out, the pilot will naturally wish to do two things:

(1) Turn the aeroplane back to good ground.
(2) Or, if he is too low down, keep the machine up in hopes of being able to reach the good ground before he has descended too far.

Turning in itself causes a great loss of speed, and a consequent loss of altitude. Even an experienced pilot will often unconsciously keep an aeroplane up too much with the elevators trying to get in good ground, and at the turn he gets the spin and nose dive into the ground he was trying to avoid. The whole of these effects exists both in stable and unstable aeroplanes.

In No. 5 this mostly applies to small, fast aeroplanes having very large engines in relation to the size of the planes. When flying at power near stalling point the swirl of the slip stream is aggravated. This swirl affects the unsymmetrical fin aft, and thus a bank is imposed on the aeroplane at stalling point so that the same condition as No. 4 is imitated.

No. 6. This case is not usual. The effect of so large a fine area aft would be got only by adding to the fin the area of the rudder supposed to be held rigid. The result of the large fin (plus rudder) area is to re-align the aeroplane too rapidly into the direction of the wind, and the remedy is to reduce the fin area by letting go the rudder control. In all the above cases the one error is bringing the aeroplane down to a point near or at the stalling speed.

Stable Aeroplane With Speed Too Slow

I will first consider outward sideslips on each of the heads given in "Unstable Aeroplane."

Nos. 1 and 2 do not exist.

No. 3. The pilot must maintain all the pressure he can exert towards keeping the rudder straight.

The aeroplane will then try to recover flying speed on its own account. It should be remembered that speed recovery means coming towards the ground, or in bad cases diving, which is not always desired by a pilot who is already down low.

Nos. 4 and 5. Considerations are as in "Unstable Aeroplane."

No. 6 does not exist.

Inward Sideslip

Having dwelt at length upon outward sideslips on stable and unstable aeroplanes, I will now turn to inward sideslips on each class of aeroplanes. An inward sideslip occurs only while stunting, except in case the pilot gets into a fog or cloud where an aeroplane may be unintentionally held on a "bank" (by any experienced pilot) yet flown with the rudder in a straight position. This gives rise to the same results as an inward sideslip due to an overbanked turn. With an aeroplane having the stability of a J N 4 B (Curtiss) the first thing to do is stop the motor. The rudder should be held over to turn the aeroplane in the direction in which it is sideslipping and the elevator control shoved forward or down. This will cause the aeroplane to dive quickly and so gain speed. As soon as the aeroplane is moving nearly vertically downward, the rudder should be brought central and elevator pulled slowly back.

I have often confirmed the above experimentally in the air and avoided bad crashes. It is unnecessary to discuss under this head the cases Nos. 1 to 6, for which the only general instruction is that the aeroplane need never be brought to the point of flying too slow if the pilot attends to business and has an air-speed indicator.

Stalling and Flying Too Slowly

One of the chief reasons for stalling, other than that indicated by an unstable aeroplane with speed too slow, occurs when an aeroplane in sight of the ground turns round from flying against the wind into flying down wind. The stalling tendency arises because of the habit of estimating the speed of an aeroplane by reference to the ground; so when going down wind the aeroplane appears to the pilot to be flying fast, though really very near its stalling speed. Thus in a 38 m. p. h. aeroplane (here 38 m. p. h. is taken as being the speed at which many aeroplanes will just avoid being stalled) against a 20-mile wind an air speed of 38 m. p. h. is safe, and is obtained when the speed over the ground is 18 m. p. h., but after the pilot has turned down wind he is safe only when making a speed of 58 m. p. h. or more in relation to the ground. The great difference of speed over the ground (or ground speed) to secure the same air speed of 38 m. p. h. is very easily overlooked, especially if no air-speed indicator is used. In these two cases the aeroplane is traveling the same air speed, but when going down wind it *appears* to be going nearly *three times* the speed as when flying against the wind. No mistake would occur in the air speed if air-speed indicators were used as extensively here as in Europe.

The usual method of purposely getting into a stall in stunting or testing is to spiral, making the spiral smaller and steeper until a spin is developed.

I have treated the above spins as "spinning nose dives." Unless a machine is diving tail first and spinning I cannot see how it is possible to call it a "tail spin." I have never known of a man to come out of a real tail spin, because the elevators will be jammed by the air pressure and the tail would necessarily be too heavy for the machine to right itself.

FOREIGN NEWS

AUSTRIA

On March 13th the Austrian official announcement reports the following aerial activity on the Italian front:

"In Venetia two Austro-Hungarian battle echelons in reprisal for enemy aerial attacks made an attack on the Italian aerodrome northeast of Mestre (a suburb of Venice). Four enemy pursuit echelons which were ready to set forth were surprised and bombed. One Italian airshed collapsed.

"On their return journey our aviators bombed Treviso and enemy trenches on the Piave."

FRANCE

According to the French official announcement of March 9th, two German aeroplanes were brought down on the previous day.

The official report issued on March 10th reports the destruction of several German aeroplanes, as follows:

"On March 9th two German aeroplanes were brought down by our pilots and ten others fell inside their own lines. It is confirmed that five German machines were brought down on March 6th and 8th. Our bombing aeroplanes carried out several sorties. Fourteen thousand kilos of projectiles were dropped on stations, cantonments and aviation grounds in the enemy zone, several fires breaking out."

Five enemy planes were downed and many bombs dropped, according to the French official announcement of March 11th:

"Yesterday five German aeroplanes were brought down or gravely damaged. Our bombing squadrons dropped 10,000 kilograms of projectiles on enemy stations and establishments in the regions to the north and east."

The French official announcement for March 12th states:

"On March 11th three German machines were destroyed by our pilots and a fourth was damaged severely. During the night of March 11th-12th three enemy bombing aeroplanes were brought down by the fire of our anti-aircraft guns."

Aerial operations are described in the announcement of the 14th as follows:

"During Wednesday a German machine was destroyed and three others were damaged severely, falling within their own lines."

The night report of the 14th says:

"During the day three German aeroplanes were destroyed by our pilots. It is confirmed that on March 9th Sub-Lieutenant Madon destroyed two German aeroplanes. Our aviators, in several sorties, recently carried out effectual bombardments, dropping 1,800 kilograms of projectiles on railway stations, works and aerodromes in the enemy zone."

The French official announcement for March 15th says:

"Last night our aviators dropped 5,640 kilograms of bombs on a number of railway stations and cantonments in the enemy zone."

The announcement of the 12th on Balkan operations says:

"Entente aviators carried out a number of raids and bombarded the enemy establishments in the region of Rupal and north of Monastir."

Reporting on Balkan operations, the official announcement of the 13th states:

"Bombing raids were carried out by Allied aviators against the railway line between Seres and Drama, on enemy depots in the Vardar Valley and against the railway station at Beranci, north of Monastir."

GERMANY

The German official announcement of March 10th states that:

"In the last two days twenty-eight enemy aeroplanes and one captive balloon have been shot down. The Boelke chasing echelon brought down its 200th opponent."

Reporting on operation of the previous day, the German statement of March 13th says:

"Vigorous reconnoitring in the air led to violent fighting. Yesterday we shot down nineteen enemy aeroplanes and two captive balloons. Cavalry Captain Baron von Richtofen achieved his sixty-fourth aerial victory."

Destruction of Allied aeroplanes in the operations of the preceding day are described in the official announcement of March 14th:

"Seventeen enemy aeroplanes and three captive balloons were brought down yesterday in aerial engagements and by fire from the ground. Of an enemy squadron flying toward Freiburg three machines were brought down on the front. Baron von Richthofen achieved his sixty-fifth aerial victory."

On March 17th the German official announcement says:

"Seventeen enemy aeroplanes and two balloons were shot down yesterday."

GREAT BRITAIN

On March 10th, British aircraft conducted a destructive daylight raid against the Daimler factories at Stuttgart. The official description follows:

"On March 10th Germany was again bombed by our planes in broad daylight. On this occasion the Daimler motor works at Stuttgart were attacked. Over one and a quarter tons of bombs were dropped. Several bursts were observed on the railway station, where a stationary train was hit and seen to be on fire.

"Three bursts were observed on a munition factory southeast of the town, and other bursts on the Daimler works and buildings around.

"Hostile machines made a weak attempt to attack our formation over an objective, but withdrew on being attacked. All of our machines returned except one, which had engine trouble and went down under control just before recrossing our lines on the homeward journey."

Successful combats and bombing activity are announced on March 12th, as follows:

"Three observation balloons were destroyed by our aeroplanes on Friday. Five German machines were downed in aerial fighting, seven were driven down and out of control, and one was brought down by infantry fire. Four of our machines are missing.

"More than 400 bombs were dropped on the Menin, Roulers, Ledeghern and Solesines railway stations."

The official night announcement of March 12th reports further bombing activity, and, among others, a very successful rail on Coblenz. The official description of the raid follows:

"There has been poor visibility, but over 500 bombs have been dropped on sidings and ammunition depots at Aulnoye, southeast Maubeuge, and other depots south of Valenciennes, southeast of Cambrai and south of Douai.

"On Monday we made the third daylight raid on Germany in four days. On this occasion factories, stations and barracks at Coblenz were attacked and over a ton of bombs were dropped. Bursts were seen on all the objectives, causing two fires, and a hit on a building in the southwest corner of the town created a very large explosion. Few enemy machines were encounterd. All of our machins returned safely."

An official statement on aerial operations issued March 13th says:

"On Wednesday afternoon nearly ten tons of bombs were dropped on munitions works and barracks at Freiburg, Germany. All our machines reached their objective.

"In addition to the raid reported in last night's official statement, over three tons of bombs were dropped on the docks at Bruges. On Tuesday bombing raids continued with greater vigor than on previous days. Over thirteen tons and a half of explosives were dropped on various targets, including railway sidings at Mons and Bavay, large ammunition depots northeast of St. Quentin and south of Douai and billets east of Lens.

"In the course of the fighting, which was continuous throughout the day, fourteen German machines were brought down and eight were driven down out of control. Six of our machines are missing.

"On Tuesday night seven tons of bombs were dropped on enemy billets between Lille and Cambrai."

Intense aerial activity is described in the official announcement of March 15th as follows:

"Aerial fighting was most severe, encounters occurring between large formations. Nineteen hostile machines were shot down and five others driven down out of control. Five of ours are missing."

"Seven hundred bombs were dropped on the enemy billets, ammunition dumps and railway sidings at Courtrai and Denain. Further reports of the raid on Freiburg say the bombs dropped were seen to burst on the railway station and around the power station. Just after bombs were released our formation was attacked by a large number of machines, the fight lasting until the enemy was forced to withdraw."

The announcement of March 17th says:

"On Sunday we again raided Germany, attacking the barracks and railway station at Kaiserslautern. Direct hits were observed on the station and a large fire broke out.

"Our formation was attacked by a large number of hostile machines, which were driven off. All of our machines returned.

"On Saturday thirteen tons of bombs were dropped on the enemy's billets, which have been bombed continuously for the last twenty-four hours, and two hostile aerodromes and three large ammunition dumps. At one aerodrome a hangar completely burst, and a Gotha machine in the act of rising was seen to crash.

"Sixteen hostile machines were brought down, and seven were disabled. Six of our machines are missing."

British aviators of the Naval Air Service on March 10th made a raid over Belgium, dropping bombs on the aerodrome and ammunition dump at Engel. Two fires were started. In aerial combats three enemy aeroplanes were destroyed and four others driven down out of control. All the British planes returned safely.

The text of the announcement of March 14th regarding the Naval Air Service reads:

"On Tuesday two British seaplanes attacked five enemy aircraft in the southern part of the North Sea. The engagement lasted thirty minutes. One enemy two-seater was shot down and destroyed, the observer of a second machine was killed and a third seaplane was driven down on the water.

"The engagement terminated when the British seaplanes had expended all their ammunition. Both machines returned safely."

On the Italian front "Five enemy aeroplanes were shot down, one by our own airmen, three by British aviators and the other by French anti-aircraft batteries. Our airships last night renewed their bombardment of enemy aviation grounds," says the official announcement of March 13th.

In co-operation with infantry, the British air forces inflicted heavy casualties on the Turks, according to the statement of March 11th.

"During the retreat the Turks were attacked by our aeroplanes with bombs and machine-gun fire at heights from 2,500 feet to under 100 feet. Heavy casualties were inflicted on the enemy."

ITALY

The Italian announcement of March 11th describes the aerial operations of the preceding day as follows:

"On Sunday our aeroplanes bombarded enemy aviation grounds. Other camps were bombed at night by five airships. A total of seven tons of bombs was dropped. All of our aircraft returned unscathed, notwithstanding the violent enemy fire. On the left side of the Piave British aviators brought down two hostile machines."

On March 14th the Italian official statement reports intense aerial activity.

"On the plains the aerial activity was intense over the fighting line and over the immediate rear lines. Seaplanes of the Royal Navy droppd bombs on enemy stores, and the aviation grounds of the enemy were bombed by our airships. One enemy aeroplane was brought down."

Naples, more than 300 miles south of the battle line, has been bombed by enemy aviators. Whether the flyers came from the Austro-German front, from the Albanian coast, 250 miles to the east, or from submarines or other craft at sea is a mystery. The attack is the first to which Naples, the largest city of Italy, with a population of 600,000, has been subjected during the war.

Mr. Schweinsberg's Model

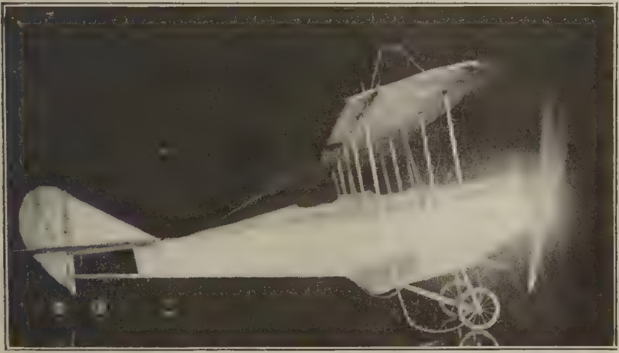
Mr. Ray Schweinsberg of Boonville, New York, sent us the following letter and photograph:

Enclosed you will find a picture of an old friend of mine. This model was built last year but has not yet flown. I have recently completed the motor tests and when the weather agrees she will take the air. I am building a 4½ foot Pursuit Plane model and I will send you a picture of it when done.

The racing model has never appealed to me. I like to make models as near large machines, with two restrictions. First, they MUST FLY. Second, they must not be so expensive that a smash will be more than a joke in time or labor. This model with its monoplane wings cost me about $10.00, as I carved the propeller myself. Then there are a few general construction rules:

> Don't use too many turnbuckles on flying models to make them look like the big ones. They are too heavy.
>
> Use spruce instead of reed on the straight wing edges. They are less likely to warp. Just before you make the corners you can join the reed with a sleeve.
>
> When you can, use tubing instead of solid rods, even for axles. They are nearly as strong and lighter.

In the pictured model I think I have used a rather new method of attachment of motor stick. The motor stick lies in the bed of the fuselage, beginning at about the deepest part of the machine and extending back nearly to the tail. The rear rubber hook is just back of the rear seat and nearly in the middle of the motor stick. The strain then comes upon all of the bottom struts, the greatest at the center, of the motor stick where they are properly braced. There is no warping and twisting of the body in this way when wound. I have spent a great deal of time in trying to persuade six foot models to take a full skein 3/16 flat without being thrown out of true. I think this is the solution.



A Unique Exhibition Model

This interesting model was made by Mr. M. S. Dunkelberger of Dayton, Ohio, particularly for store window display purposes.

The body is constructed of light tin and is 32 inches in length, containing a 110 volt electric motor for operating the propeller and the rear planes. Aviators are represented by ordinary dolls with headgears, which were cut from light leather, securely glued to their heads. A painted mustache makes them appear to be of fighting age. Windshields are of celluloid.

The propeller is 9" in length and was fashioned from poplar and given several coats of hot glue and shellac.

Wheels are of wood construction with rubber rings for tires.

The wing framework is of light wood and wire covered with linen doped with shellac. The top wing measures 6" x 39", the lower wings 6" x 12" each. Struts are of light wood and fit in small sockets, which are soldered to the wing framework. By cross wiring the wings they are made rigid and can be disconnected from the fuselage as shown by the enclosed photo.

The model is painted a war gray and lettered in black. Insignia on wings and fuselage is painted in the familiar red, white and blue. The rudder is also painted red, white and blue.

To complete the window display, Mr. Dunkelberger painted a scene representing a training camp "Somewhere Behind the Lines," and with green sawdust and sand transformed the floor into a good field.

In operating a flasher is used, which automatically starts and stops the motor, giving the onlooker a chance to see the construction of the propeller.

A Compressed Air Motor for Model Aeroplanes

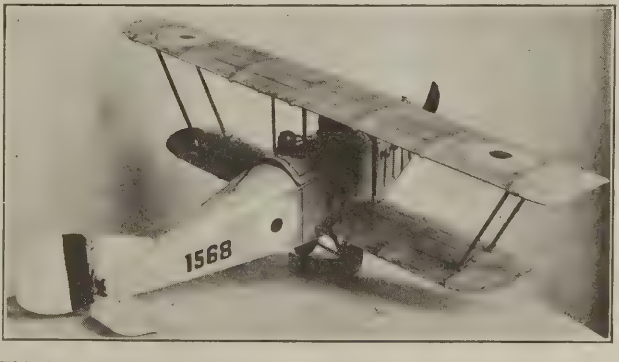
(Concluded from page 59.)

Assembling

As simple as this type of engine may seem, it nevertheless calls for carefulness and judgment, especially in the matter of assembling the various parts, for it is quite possible that a few finishing touches will be needed to enable the completed product to work efficiently. Patience likewise is essential to good results. First, see that the pistons function smoothly in the cylinders, then attach the cylinders one to the other by lapping over the other in the manner illustrated in Fig. 1-a, and solder into place. Through the center of the ends thus lapped a hole should be bored ¼" in diameter into which one end of the valve casing should be soldered. Inlet pipes can be formed from two pieces of brass tubing ⅛", Fig. 1, e, e, and after heated until soft should be twisted to a shape similar to that shown. One end of each piece of tube must be soldered to the end of a cylinder, while the other end should be soldered into the second hole of the valve shaft casing. Continue by inserting the valve shaft into the valve shaft casing and follow by springing the connecting rods onto the crankthrow. To protect the propeller from the end of the valve casing and at the same time serve as a flange for mounting the propeller a small metal disc should be soldered one-half inch from the end of the valve or crank shaft which protrudes from the end of the casing.

It is quite natural that the engine will operate rather stiff, but this stiffness can be worked out by oiling the various parts and working the engine in the following manner: Fix the engine to remain stationary, clasp the end of the crankshaft in the jaws of a drill and turn until the engine there is a minimum amount of friction. The final operation consists of connecting the engine with the tank. This can be done by using a piece of brass tube 3" long by ⅛" in diameter and bending it into an oval shape, as illustrated, Fig. 1, e. e. When the ends have been soldered into the holes nearest the cylinders, bore a hole into the tubing halfway between each end. Do not bore the hole through. To complete the work, cut off another piece of ⅛" brass tubing and solder one end to the inlet valve in the tank and the other to the hole just drilled.

In conclusion perhaps it is necessary that a little advice be given to the extent that too great a pressure should be avoided when first attempting to charge the tank with air, for it sometimes happens that the soldering is not complete, in which case undue pressure may cause unnecessary damage, which can be obviated if, after a slight charge, say, 10 strokes of the pump, has been given, the tank is carefully examined for possible leakage. And again, don't get discouraged if at first chance the engine does not perform as desired, for it may be necessary to readjust some of the parts, and by so doing the builder is afforded a splendid opportunity for cultivating inventive ability.



This interesting reproduction of a large military aeroplane is now being exhibited by Mr. Dunkelberger, in several large stores of Dayton, Ohio.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Important Notice!

A letter of great military importance has fallen into the hands of the Aeronitis editor, which proves that Germany has lost all hopes of winning the supremacy of the air.

"DEAR MOTHER:

"Just a line to say that I have joined the *Verkhestruppen*[1] and by authority of the *General Inspektion des Militar-Verkhrsweseus*[2] was given a commission in the *Lufstreitkrafte.*[3] On reporting to the *Kommandierender-General der Luftstreitkraft,*[4] I was detailed to the *Fliegernachrichtenoffizier,*[5] who ordered me to the *Inspektor der Fliegabwehrkanone im Heimgabiet.*[6] The constantly increasing *Kampfeschwader*[7] of the Allies has greatly increased the work of our *Schutzstaffen.*[8] Although we have numerous *Seefliegerabteilungent*[9] and *Landliegerabeteilungen,*[10] they are far from sufficient. Allied *Feldfleigerabeteilungen*[11] and *Artilleriefliegerableilungen*[12] fly unmolested, protected by their *Jagdstaffeln*[13] and *Schutstaffen.*[8] Our best efforts are insufficient.

"FRITZ."

"We'll Keep Flying"

Alonzo Newton Benn, a Chicago Athletic Association Member, Has Published a Patriotic Song Entitled, "We'll Keep Flying." It Was Especially Written for Cornell Alumni, and Follows:

We'll build a million avyplane,
  To fly across the ocean;
And when (s)hell-fire begins to rain,
  There'll be a big commotion.
We'll fly above the clouds so high,
  Hun guns our flight can't hinder;
And when we drop our bombs quite nigh,
  They'll hustle for tall timber.

We'll chase the boche back o'er the Rhine,
  They'll go all helter-skelter;
And march no more to goose-step time,
  As they hot-foot for shelter.
We'll pilot straight for old Berlin,
  To bomb the kaiser's palace;
And make him rue his hellish sin,
  Of burning church and chalice.

Aeroplane Propeller Stock

Toothed at the rate of 100 feet per minute by running it through a

WHITNEY
Toothing Machine

If you want to prepare your Propeller stock before gluing up by the quickest—easiest—safest and cheapest method, just put it through a Whitney Toothing Machine.

Many of the Aeroplane Manufacturers, as well as Propeller Makers, are using this machine.

It will pay you to investigate.

Lafayette Flying Corps Honors Aero Club

The Aero Club of America has just received the diploma of the Lafayette Flying Corps, which has been awarded to the club for its patriotic service in collaboration with the Lafayette Corps. This beautiful engraving depicts the figures of Marquis de Lafayette on one side, and on the other the illustrious George Washington, first President of the United States. Aerial combat is shown in the sky, while below are the anti-aircraft guns firing amid the battle-scarred ruins of the devastated districts below.

This diploma has been given at various times to members of the corps for distinguished service and the Aero Club of America considers it one of its greatest honors to have received this recognition of the work it has done in giving its moral support to the corps and in assisting in sending many young men to France to fight for the cause which the whole nation is fighting for now, at a time when there was some hesitation on the part of the country as a whole in taking this momentous step and declaring war upon the German nation. The Lafayette Flying Corps has made a record of which America may well be proud, and which has strengthened the bonds of union between the Republic of France and ourselves.

The Honorary President of the Lafayette Flying Corps, Mr. William K. Vanderbilt, transmitted this diploma through Major Edmund L. Gros, the Vice-President of the Lafayette Flying Corps, and also member of the Foreign Service Committee of the Aero Club of America, which has been formed to keep in touch with American fliers in Europe, whether in the service and out of the service, and to keep the Aero Club of America informed as to their welfare, their needs and to render emergential aid to aviators, and to give their relatives and friends all available news of their welfare at all times within the necessary military restrictions. The American Ambassador, Hon. Wm. G. Sharp, is the Honorary Chairman, Mr. Laurence V. Benet, who has just been made a Chevalier of the Legion D'Honneur for his valuable and patriotic work in connection with the American Ambulance, is the acting Chairman, and Mr. Sidney B. Veit, one of the oldest members of the foreign colony, and for a long time on the Foreign Relations Committee of the Aero Club of America, is the Secretary.

The Foreign Service Committee of the Aero Club of America has arranged for the striking of the special war medal of the Aero Club of America, which was designed by the famous medallist Pierre Roche, who has lately been selected as one of the four artists to submit designs for a medal to be struck commemorating the entry of the United States into the world war. The special war medal of the Aero Club creates a new allegorical figure—an "Aero-maid," symbolizing aerial navigation by the pinions upon which she is borne, and, as the illustrious Pierre Roche intends, representing the tenth muse,—the "Muse of the Air." An inscription in Latin "Coeli Colis Stellarum Corona"—"To the heroes of the skies, a crown of stars" is most appropriate as it will be awarded for distinguished military service. Forty-eight stars, encircling the "Aero-maid," represent the forty-eight states of the Union, and thirteen, representing the thirteen original colonies, form the crown. This medal has already been awarded to Major Raoul Lufbery, the American ace, Major Wm. Thaw, to the families of the American volunteers, members of the Lafayette Corps, who have died for France and to the father of Captain George Guynemer, and to Lieutenant Charles Nungesser, of the French Army, Lieut. Ball of the British Army, Major William Avery Bishop, the Canadian flier, Captain Barraca, of the Italian Army and Lieut. Thierry of the Belgian Army.

The Foreign Service Committee has also distributed large quantities of tobacco, literature and necessities to the aviators at the various camps and those stationed in Paris, and they have sent clothing and money to the aviation prisoners in Germany, and have assisted in the arrangements made for sending Lieut. Henri Farre official painter of the French Army and Navy Aerial Warfare to this country, exhibiting a new school of painting, giving all those who see the paintings a realization of being in the air itself and being one of those taking part in the aerial combats which he so realistically depicts.

Research Information Committee, With Branches in London and Paris, Formed, Defense Council Announces

The following statement is authorized by the Council of National Defense:

1. By joint action the Secretaries of War and Navy, with the approval of the Council of National Defense, have authorized and approved the organization, through the National Research Council, of a Research Information Committee in Washington with branch committees in Paris and London, which are intended to work in close cooperation with the offices of the Military and Naval Intelligence, and whose function shall be the securing, classifying, and disseminating of scientific, technical, and industrial research information, especially relating to war problems, and the interchange of such information between the allies in Europe and the United States.

Organization of Committees

2. The Washington committee consists of—

(a) A civilian member, representing the National Research Council; Dr. S. W. Stratton, chairman.

(b) The chief, Military Intelligence Section.

(c) The Director of Naval Intelligence.

3. The initial organization of the committee in London is—

(a) The scientific attache representing the Research Information Committee; Dr. H. A. Bumstead, attache.

(b) The military attache, or an officer deputed to act for him.

(c) The naval attache, or an officer deputed to act for him.

4. The initial organization of the committee in Paris is—

(a) The scientific attache representing the Research Information Committee, Dr. W. F. Durand, attache

(b) The military attache, or an officer deputed to act for him.

(c) The naval attache, or an officer deputed to act for him.

Functions of Foreign Committees

5. The chief functions of the foreign committees thus organized are intended to be as follows:

(a) The development of contact with all important research laboratories or agencies, governmental or private; the compilation of problems and subjects under investigation; and the collection and compilation of the results attained.

(b) The classification, organization, and preparation of such information for transmission to the Research Information Committee in Washington.

(c) The maintenance of continuous contact with the work of the offices of military and naval attaches in order that all duplication of work or crossing of effort may be avoided, with the consequent waste of time and energy and the confusion resulting from crossed or duplicated effort.

(d) To serve as an immediate auxiliary to the offices of the military and naval attaches in the collection, analysis, and compilation of scientific, technical, and industrial research information.

THE HOUSE OF MARTIN STANDS
FOR SUPREMACY IN PERFORMANCE

(e) To serve as an agency at the immediate service of the commander in chief of the military or naval forces in Europe for the collection and analysis of scientific and technical research information, and as an auxiliary to such direct military and naval agencies as may be in use for the purpose.

(f) To serve as centers of distribution to the American Expeditionary Forces in France and to the American naval forces in European waters of scientific and technical research information, originating in the United States and transmitted through the Research Information Committee in Washington.

(g) To serve as centers of distribution to our allies in Europe of scientific, technical, and industrial research information originating in the United States and transmitted through the Research Information Committee in Washington.

(h) The maintenance of the necessary contact betwen the offices in Paris and London in order that provision may be made for the direct and prompt interchange of important scientific and technical information.

(i) To aid research workers or collectors of scientific, technical, and industrial information from the United States, when properly accredited from the Research Infromation Committee in Washington, in best achieving their several and particular purposes.

6. The headquarters of the Research Information Committee in Washington is in the offices of the National Research Council, 1023 Sixteenth Street; the branch committees are located at the American Embassies in London and Paris.

VOL. VII NEW YORK, APRIL 1, 1918 No. 3

CONVERT $3,000,000,000 OF LIBERTY BONDS INTO WARPLANES AND THE ALLIES' VICTORY WILL BE ASSURED

"THERE is only one weapon that can outdistance and destroy whatever weapon the Germans may be using against Paris, and that is the battleplane. We must extend our manufacturing facilities by using plants that are practically idle for lack of orders and proceed as fast and as far as we humanly can with an air program substantial enough to insure continuous delivery of aircraft in substantial number.

"As the situation stands, aircraft manufacturers have no orders to look forward to and some are not working to their full capacity.

"The Air Service is without funds with which to expand; it has been for a number of months; therefore, we are still working on the air plans made at the time when Italy was victorious and Russia was fighting, and there are not even the necessary funds to hasten this plan.

"It is up to Congress to act, and unless it does act promptly we will lose all possibilities of making ourselves felt in the air this year—and may pay a heavy price for our failure to act.

"The sum of $3,000,000,000 is needed for the Air Service, to provide the two machines per aviator needed for training and a minimum of six machines per man per year to keep them fighting. It makes a total of 80,000 aeroplanes and about 250,000 motors that we must provide to train and equip ten thousand aviators.

"We should have started at least six months ago, when Italy began to suffer losses and the Russian collapse became evident. We must lose no more time. The matter is too vital to the welfare of the Republic and the cause of the Allies."

Thus Mr. Alan R. Hawley, the president of the Aero Club of America, summarizes the situation.

We must act, and act promptly. Every person can help by subscribing to the coming Liberty Loan. Liberty bonds, converted into warplanes, will win the war.

GENERAL WOOD, BACK FROM FRANCE, URGES RUSH IN BUILDING AEROPLANES AS ONE OF THE MOST ESSENTIAL FEATURES TO WIN THE WAR

JUST back from the fronts, General Leonard Wood, the father of the National Preparedness movement, urges rush in building aeroplanes as one of the most essential features

Just back from the fronts, General Leonard Wood, the father of the National Preparedness movement, urges rush in building aeroplanes as one of the most essential features to win the war.

This recommendation was made to the Senate Committee on Military Affairs on March 25.

The New York *Times* gives the following resumé of General Wood's testimony and advices:

"Members of the committee were amazed when General Wood told them that not one American aeroplane was in use by the American forces in France. America has been supplying machines to England, but has not shipped any to her own men. The Germans have the ascendancy in the air over the American sector, the General said, the Americans being entirely dependent upon what machines the French are able to give them.

"Associated Press dispatches from the American front telling of the freedom with which German aeroplanes flew over the American lines, owing to the lack of American aeroplanes with which to combat them, were confirmed by General Wood. The French fliers on both sides of the American sector have been protecting the American front against enemy airmen, the General said, but at times they are too busy elsewhere to afford adequate protection, with the result that the German aeroplanes have absolute freedom. At times, he said, the Germans flew so low that the Americans were able to fire at them with revolvers.

"General Wood urged that America rush the work of building aeroplanes as one of the most essential features of its part in the war. He spoke of 1,000 American airmen being with the American forces, but with no machines of American make to fly.

"In reply to questions put to him by the committee, General Wood said the new Liberty motor was regarded by experts in France as unsuited to combat machines. Its utility, the experts believe, according to the General, will be confined chiefly to machines used in bombarding. He urged that parts of aeroplanes be shipped to France and aeroplanes made there.

"General Wood declared that, although there were no American heavy guns or shells of any character to supply the American forces in France, the French and British were able to make up the deficiency. While advising that America ship guns and munitions to France, he said that no handicap would result to the American troops so long as France and Britain could keep up the supply, and they were able to do it indefinitely.

"With a much greater American army in France, entailing increased demands for guns and ammunition, the General said, America would be called upon to furnish an appreciable part of her own ordnance. But for the immediate army and for the number of men apt to be in France in the next few months there are plenty French and British gun and shells.

American Morale Superb

"The General referred to the morale of the American troops as superb. The men have quickly adapted themselves to their new environment, he said, and make superior soldiers. They compare most favorably with the veteran French and British fighters.

"In commenting upon the disappointment of the French and British over America's lack of preparedness, General Wood explained that they had thought America, with her vast resources, would give a powerful impetus to the allied fighting machine. America had been depended upon not only for ships, but aeroplanes, while it was believed that if men were needed they would be forthcoming. The Allies were surprised, he said, that it took the United States so long to get into her fighting stride.

"Ships, and more ships, the General said, were necessary to win the war. Tonnage is required not only to transport American troops, he said, but to convey their supplies, as well as supplies to the Allies.

"General Wood gave confidential data to the committee bearing upon the necessity for ships and men. Asked by a member of the committee if he favored compulsory training for Americans between the ages of 19 and 21, the General replied that it seemed 'sound.'

"Men, ships and artillery, in the order named, the General is said to have stated, are the principal military needs of the Allies from America. In urging the necessity for more ships, General Wood criticized the present shipping arrangements, and said he had suggested to the War Department that fast and slow ships be segregated in the convoys, so that fast ships would not be held back by the slower vessels.

"The breakdown of Russia has greatly improved the morale of the German Army and the German people, General Wood said. He added that America should pay more attention to the Italian situation, and suggested that Americans of Italian origin be sent to Italy to combat the German propaganda, which has been active in that country.

"'General Wood fully discussed the situation from the time he left this country up to his return,' said Chairman Chamberlain, after the conference. 'He felt that the American industrial program should be pushed and not slackened in the least. He thought, also, that more raw materials might be sent abroad to be manufactured in France, and that, I understand, is the policy of the War Department—to increase shipment of raw articles for French manufacture.'

"Strengthening of the Army General Staff also was urged by General Wood. So many former experts on the General Staff, he said, have gone to France that, while General Pershing has a splendid staff, the War Department has been depleted and should be built up for advisory purposes."

GUN OR AERIAL TORPEDO?

IS it a gun or an aerial torpedo that is shelling Paris?

The latter seems more probable. The Aero Club of America authorities explain why as follows:

"It does not seem possible," said Mr. Alan R. Hawley and Henry Woodhouse, "that a gun has been developed that will have a range of more than thirty miles. There are fundamental factors upon which long-range gunnery is based. To get long range there must be a very high muzzle velocity, which depends upon the kind and amount of explosives used.

"The effect of a large charge of explosives is an enormous recoil. It would seem that if extraordinary guns had been developed able to shoot seventy miles, the recoil would be so enormous that the gun would be rendered useless after a few shots. It is inconceivable that such a gun has been developed.

"But it must be remembered that the inventive genius of the world has been mobilized and we must expect certain new instruments. We find that the shelling of Paris may have been done in any of four ways.

"A new, gigantic long-range gun hidden in forests within thirty-five miles of Paris could be used. It does not seem possible the enemy could hide a weapon so close, however.

"Large aerial torpedoes equipped with wings, launched into Paris from almost any distance, possibly guided by wireless control, could be the explanation. A great many wireless and motor-driven torpedoes have been invented.

"Aerial torpedoes could have been dropped from a height of more than 25,000 feet, so high the machines from which they were dropped could not be seen. The Germans have been developing light aeroplanes for high altitude work. This would account for some of the shells hitting Paris in different sections of the city. The course of such torpedoes would be changed considerably by air currents on the descent.

"Aerial torpedoes, especially built, could be shot from the huge German aeroplanes equipped with four motors, reported as being under construction in recent despatches. Shooting aerial torpedoes from a height would require little muzzle velocity."

The club authorities declared they believed the report that the Germans were shelling Paris from a distance of seventy miles was untrue and was being circulated to detract attention from the actual means employed.

FRENCH SEE NEED FOR INDEPENDENT AIR SERVICE FOR MAJOR AERIAL OPERATIONS AGAINST GERMANY

ONE of the consequences of the recent air raids on Paris, according to a special dispatch to the New York *Times*, has been a demand for a more aggressive policy against German air bases, such as was suggested to *The Times* correspondent by prominent aviation officers at the Belgian front last November. It is beginning to be realized that reprisal raids on the nearest German towns are unlikely to deter the enemy from bombing the French and British capitals. The only effective reprisals would be against Berlin, which is at present beyond reach of attack by an adequate air force.

An evidently inspired article in Premier Clemenceau's newspaper today makes the direct assertion that Germany's whole object in the Paris raids is to force the withdrawal of allied aeroplanes from the front in the hope of redressing her own inferiority in the air, which is daily growing more evident. In proof of this last assertion the writer compares the figures of the destruction in recent weeks of allied and German aeroplanes, and says, (italicizing the words:) "On point of military importance in the war zone ten bombs are dropped by allied aeroplanes for every one dropped by the Germans."

The correspondent is informed that part of Air Minister Dumesnil's statement before the Army Committee of the Chamber of Deputies concerned action against enemy airdomes. In the last two raids strong French bombing squadrons attacked the "nests" from which the Gothas set out, and apart from the destruction of hangars, barracks, and repair shops, the ground on which the Geman machines had to land was thoroughly plowed up by bombs, the measure of whose efficacy will be readily admitted by any one who has experienced the difficulty of a night landing in the best of circumstances.

There is also a suggestion in L'Oeuvre from Deputy Flandin, a member of the Army Committee, who has always paid special attention to aviation, which may well be a consequence of Dumesnil's statement. M. Flandin strongly advocates a regrouping of all aerial activities into a separate service as free from purely military control as the navy. He says:

"Why not constitute an independent high command and a General Staff of the air army to organize the war in the air just as the army and navy chief direct operations on land and sea? Their action would enable us to oppose the enemy's program of intimidation by an energetic scheme of a counter-offensive. There is no better means of protecting Paris against new attacks."

On similar lines was the following statement made to the New York *Times* correspondent yesterday in the lobby of the Chamber by an ex-Minister:

"I learn that a great measure of the recent British air successes has been due to improved organization as the result of the formation of naval and military aviation forces into what might be termed an autonomous service. It is for us to take a leaf from the English book and recognize that the war in the air may be even more decisive than operations on terra firma. At any rate, it seems the only direction in which we are likely to have marked superiority over the enemy this year."

At this date, when support in the air is awaited here as one of America's greatest contributions to the allied effort, this question of air service autonomy is no less important to America than to France or England. Now is the time to plan our organization instead of waiting, as our allies have done, until forced to do so by the pressure of circumstances.

THE NEWS OF THE WEEK

House Committee Reports on Naval Aviation

A special committee of the Committee of Naval Affairs of the House of Representatives reported on the Naval Aircraft situation as follows:

"We have examined the naval aircraft situation and find many matters of great interest, but much of our information is not now open for public discussion. This was the one development of material which no amount of foresight would have enabled the Navy to prepare adequately. The growth of aeroplanes and hydroaeroplanes has been so rapid that nothing short of actual war conditions would insure a large number of up-to-date machines with aviators trained to handle them. In the earlier stages of its undertaking the Naval Air Service met many discouragements, but the perfection of the Liberty motor and the use of large sums of money in conjunction with the Army to finance manufacturers have, under the direction of the Air Service, produced results that promise to meet the requirements of this important branch of the Navy."

E. C. Bass Marries Daughter of Baroness De Montaru

Mr. E. C. Bass, a well-known English aviator, who has been engaged for the last two years in important experimental aviation work in the United States, married Miss Xenia Greville Moore, daughter of the Baroness de Montaru.

Mr. Bass, who is registered as hydroaeroplane pilot No. 9 by the Aero Club of America, was one of the first to experiment with the Curtiss flying boat and, with Glenn H. Curtiss and John D. Cooper, took the first flying boat to England in 1913. Mr. Bass was closely connected with the development of the British submarine-chasing flying boats early in the war. Recently he has been working on a camera gun, which is capable of taking 750 pictures per minute.

Congressman Aviator in Aero Accident

Ex-Congressman La Guardia, now a Captain in the American Air Service, was injured in an aerial accident, according to a message from Rome.

Patriotic Meeting in Carnegie Hall Under Aeronautic Committee of Woman's Naval Service

A lecture by Capt. R. Hugh Knyvett, entitled "Making the World Safe for Democracy," was delivered at Carnegie Hall Friday evening, March 22, under the direction of the National Aeronautic Committee of the Woman's Naval Service.

Captain Knyvett is an Australian and has seen three years of active service at the front in Egypt, Gallipoli and France. He is now in America on leave, recuperating from wounds received from German bombs at Bapaume.

The members of the aeronautic committee of the Woman's Naval Service are Mrs. E. H. Harriman, Mrs. Clinton Gilbert, Mrs. Melvin L. Bronson, Mrs. William E. Benjamin, Mrs. Horatio N. Slater, Mrs. French Vanderbilt, Mrs. William H. Crocker, Mrs. Marshall Russell, Mrs. Benjamin Thaw, Mrs. Charles H. Whitman and Mrs. Henry Wise Wood. Mrs. Charles A. Van Rensselaer is chairman.

Big Plants Insure Against Aeroplane Bombs

The big gas and electric lighting companies of New York have arranged for insurance in excess of $50,000,000, covering bombardment from the air or the sea and other forms of war risk.

$40,000,000 worth of the total insurance has been taken by the Consolidated Gas Company, whose plant comprises one of the most valuable properties in the city. From $7,0000,000 to $10,000,000 has been taken by the New York Edison Company. $3,000,000 is said to have been taken by the United Electric Light and Power Company, although the correctness of this sum has not been confirmed.

In their decision to insure against loss from enemy attack, the big lighting companies have followed the example of a number of other large New York concerns who since the outbreak of the war have insured themselves against invasion to an extent, estimated by Howard P. Moore, Assistant Secretary of the Home Insurance Company, at close to $200,000,000.

The number of applications for this form of protection coming to the insurance companies has been constantly increasing the past few weeks. Mr. Moore ventured that there were at least a dozen concerns in New York carrying from $2,000,000 to $5,000,000 in war risks.

Navy Department Tests Liberty Motor

The first Liberty motor to reach Washington in actual service has arrived, driving a navy flying boat from Norfolk and carrying the pilot and two passengers. The trip was made in approximately two hours, despite the fact that the boat got off the 175-mile course mapped out, and covered a considerably greater distance. No trouble whatever was experienced with the Liberty engine.

The boat, one of the smaller types for sea service, has not been placed on exhibition while here. Navy officials are highly satisfied with the performance of the motor, however, and further long-distance tests are to be expected.

The crew of the boat accompanied department officials on an inspection trip today to witness the performance of the larger type flying boat equipped with two Liberty motors.

The navy type Liberty motor is not fitted to develop the same power as the type used in land machines. Flying boats or hydroaeroplanes are not designed to maneuvre at the high altitudes of the army craft and the same piston compression is not necessary. The Liberty supplies 50 horespower in excess of the estimated needs for the navy air service.

Police Prepare for Air Raids Over New York

A new organization of the Police Department will be tried out soon in New York under the direction of Borough Police Inspector William O'Brien, so that New York City may be prepared for air raids.

Besides members of the Police Department, the organization comprises physicians, surgeons, nurses and helpers designated by the Health Commissioner. Each police station is headquarters for the precinct unit, and there are to be stored stretchers and all necessary medical and surgical supplies. Temporary dressing rooms are to be fixed up in each station, from which the wounded are to be sent to a designated hospital.

When an air raid comes, according to the plans already worked out, certain manufacturing plants will blow a designated signal, as an alarm to the relief workers. These workers will be card-indexed and will be called by telephone from the station if they do not respond promptly to the siren alarm. All ambulances and the owners of motors and trucks available for the volunteer work will also be listed for hurry calls.

This temporary organization is the result of a suggestion made to Police Commissioner Enright by Captain A. Wells Ingram, a British officer attached as lecturer to the American Red Cross at present. Captain Ingram has been in thirty air raids in London, Paris and Belgrade.

"We believe it quite possible for aeroplanes to be launched from the deck of submarines," said Mr. Woodhouse, member of the Board of Governors of the Aero Club of America. "U-boats have been employed for this purpose right along in European waters. The only hindrance in bombing New York, for example, would be the distance to be travelled by the U-boats. If the German submarines can reach here—and they have demonstrated they can—they can launch their hydroplanes at us.

"And Germany, I believe, will try it. She will do it, in the first place, with the idea of throwing terror into this country. Then she is so clever she can see the utility of such a raid in making sensational news screamers to be handed out to cheer up the German people and spur them on in the war."

Air Sections Move Quarters

Last week a number of the sections of the Air Division of the Signal Corps, Washington, D. C., was moved from their former locations in different parts of the city to the Arcade Building, 14th Street and Park Road, and it is understood to be the intention, as far as possible, to consolidate all the sections and divisions of the Air Division in this building.

Aviators who bombarded New York City with thrift literature, and Mrs. Burke Cockran and Mrs. Wm. R. Hearst, who were prominent in arranging the demonstration.

American Aviators in Italy Fly 212 Miles in 158 Minutes

Two American aviators accomplished on March 15th a fast flight from Foggia to Rome, flying the 212 miles in 158 minutes.

The aviators were Major Ryan, commander of the American Flying Corps at Foggia, who acted as pilot, and Captain Frost, who made the trip as observer.

Royal Flying Corps' Recruiting Bureau Has New Head

Lieut. Theodore Marburg, Jr., a native of Baltimore, and son of Theodore Marburg, ex-United States Minister to Belgium, has succeeded Major Lord Robert Innes-Ker, in charge of the recruiting depot of Royal Flying Corps, at 220 West 42nd Street, New York City. Lieut. Marburg was at Oxford when war was declared. He joined the Oxford University Officers' Training Camp in October, 1914, and was commissioned in the Royal Flying Corps in the spring of 1915.

After establishing a good record as a fighting airman, Lieut. Marburg lost a leg in an accident in December, 1915. After six months' leave, he qualified as a pilot a second time, and, notwithstanding the loss of his leg, is still an expert airman.

At the American Aviation Training Camps

Lieut.-Col. Hensley is to organize and command the new training school for balloon observers soon to be established on the "Lucky" Baldwin ranch, near Los Angeles, Cal. Last year he was placed in charge of the Fifth Balloon Squadron, at Fort Omaha.

First Lieut. Walter J. Johnson for whom there is a star in the service flag displayed by the banking house of J. P. Morgan & Co., was killed last week by falling 1,500 feet in an aeroplane at Kelly Field, near San Antonio, Texas. His parents, Mr. and Mrs. Michael H. Johnson, of No. 99 Highland avenue, Jersey City, received an official telegram from the War Department announcing the young man's death.

Lieut. George B. Post, Jr., was named as the Commander of the 83rd Aerial Squadron, displacing Lieut. Harry M. Winner, who was made Commander of the 203rd Aerial Squadron, now being organized at Chanute Field.

Augustus Post Lectures

On March 20th, Mr. August Post, Honorary Secretary of the Aerial League of America, addressed the Institute of Arts and Sciences, at Havermeyer Hall, Columbia University. The hall was filled to capacity. The subject of his address was "With the Sky Fighters."

Mr. Post delivered an address at the Anderson Galleries on the "Devastated Districts of France," on March 21st and 22nd.

The Fort Schuyler Club of Utica, New York, on March 23rd had the privilege of having Mr. Post as the chief speaker of the evening of March 23rd.

Lieut. Flachaire Flies in Washington

Lieut. G. Flachaire, one of the French "aces," ordered to this country to assist in the work of training American fliers, gave Washington a daring exhibition of the various acrobatic maneuvres now deemed necessary for successful solo work. He flew a Spad machine, the equipment furnished French aces for their air contests with the German champion aviators.

Speaking of accidents during training, he said to a newspaper correspondent that: "The losses in the schools are useless losses. They can be reduced by strict discipline, by the use of good instructors and by forbidding acrobatic flights until the pilot has absolutely mastered his art."

Wilkinson Will Test Liberty Motors

John Wilkinson, vice-president and consulting engineer of the Franklin Motor Company, has been named as the third member of the committee which is to test the Liberty motor. The other members are H. M. Crane, chief engineer of the Wright-Martin Aircraft Corporation, and designer of the Crane-Simplex motor, and D. McCall White, the designer of the famous Cadillack "8."

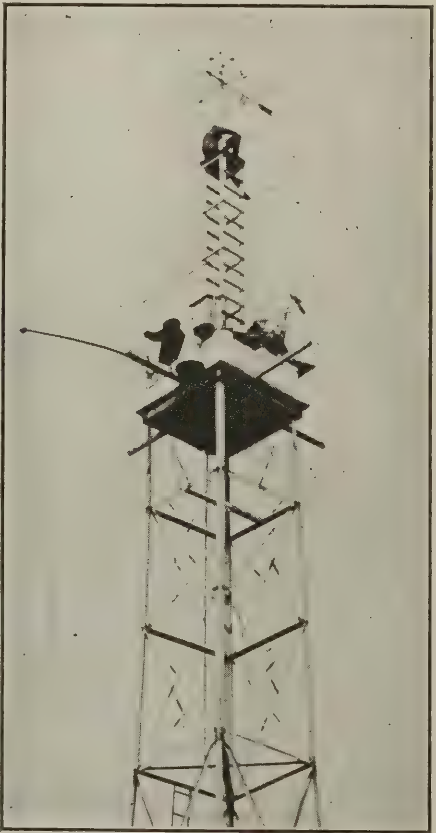
U. S. to Take Over Timber Land

The Senate discussed briefly the bill proposed by the Administration for commandeering forests and lumber supplies of the United States which was favorably reported several weeks ago by the Senate Committee on Military Affairs and later withdrawn for revision. Chairman Chamberlain of that committee, back on duty after his recent illness, volunteered an explanation of the necessity for the Government assuming control of the whole problem of timber supply by saying there had been great difficulty encountered by reason of I. W. W. activities in the Western lumber country.

State Senator Morris S. Halliday, of Ithaca, N. Y., is resigning his position to enter the Air Service.

"I do not know," said Senator Chamberlain, "whether they have been guilty of any overt acts either in destruction of lives or property, but conditions grew so desperate in Oregon and parts of Washington that men were afraid to go into timber to work. It became necessary to send military men out there, and it did not become possible to insure the production of lumber as demanded by the Government until men from Camp Meade, with rifles on their shoulders, were at hand to see that the work was carried on and that interference by the disorganizers was prohibited."

Athletic Equipment for Aviators



Observation tower at Naval Aviation Station, Warrington Beach, Pensacola, Fla., from which flying instructors observe work of student aviators. (Committee on Public Information.)

Men of the aviation service, by reason of their nerve-wracking work, must have complete relaxation when not on duty, and this relaxation is best attained through athletic contests of all sorts. In order to raise sufficient money to furnish each unit going abroad with athletic equipment, the National Aeronautic Committee, of which Mrs. Charles A. Van Rensselaer is chairman, is arranging a concert-dinner-dance, to be given in the Crystal Room of the Plaza sometime in April.

"We have equipped within the past few weeks," said Mrs. Van Rensselaer, "forty-six squadrons, but now our aid has been asked by the officers commanding the outgoing aviators to increase this supply vastly. We should be able to provide eighty outfits a month, but as each outfit costs $250 we are making an appeal to other patriotic citizens to join us in raising the large sum necessary."

Wardrop Addresses "The Round Table" and Other Organizations

G. Douglas Wardrop, the editor of "Aerial Age Weekly," addressed the "Round Table" at Columbia University on the subject of aerial warfare.

During the past week he has also addressed the combined Engineering Societies of Yale, the Quaint Club of New York, the Draco Club of New York and the Engineering Society of Providence, Rhode Island.

Evan J. David Addresses Cleveland Engineers

Evan J. David, business manager of "Flying," addressed the members of the Cleveland Engineering Society on "Aircraft in Warfare." The audience was thoroughly representative of all the engineering interests in Cleveland, and very keen interest was shown in Mr. David's lucid presentation of the subject.

The Resistal Goggle Controversy

Subsequent to the appearance of a despatch in a New York newspaper purported to come from the Rockwell Field at San Diego, Strauss & Buegeleisen, the manufacturers of Resistal goggles, have issued the following statement:

"The newspaper account in some papers made an alarming statement that a German conspiracy or plot had resulted in the manufacture and supply of defective goggles for use by aviators. The accounts related that bad landings and many accidents in landings had been caused by these defective goggles. In some newspapers, the name was given of the goggle and in others it was omitted, but, of course, the goggle referred to in each case was the Resistal goggle.

"It is most important that first of all it be thoroughly established that Strauss & Buegeleisen are not Germans, nor have they any Germans in their employ, the entire concern being American and all of its employees being American. It will be noted that Strauss & Buegeleisen are a young cooncern, composed of young men throughout and that they have absolutely no connection at all with anything that is German.

"The reports appearing in the paper were without foundation as they have been denied by Major Bartholf, commander of Rockwell Field at San Diego and by him also for Major John Purroy Mitchel, in the following telegram received from Major Bartholf by Strauss & Buegeleisen on March 25th:

> "The report that I have ordered the destruction of Resistal is entirely erroneous. Major Mitchell states that he has made no discovery or statement concerning Resistal, and that any such reports are without foundation. No official statement was given to any paper in regard to this matter."

"It appears, however, that the occasion for sending out this report was the receipt by the various camp commanders of a report issued by the Signal Office in Washington. This report recites entirely the findings of A. L. Day of the Carnegie Institute.

"Day's arguments were submitted to the Signal Corps in November 1917, but were not embodied in this official letter until March 12th.

"In the meanwhile, Strauss & Buegeleisen managed to induce the National Advisory Committee on Aeronautics, the Signal Corps and the Bureau of Standards to investigate the subject of aviator goggles and protective glasses, which investigation was begun by the Bureau of Standards Laboratory on March 1st.

"Their report, dated March 25th, recording Bureau of Standards test No. 23,004, is concluded with the following paragraph:

" 'The relatively increased nonshatterability of laminated glass and its comparatively good transparency and rigidity, even after fracture should be of great importance in devices for protecting the eyes and face.'

"It will be noted that this finding is directly contrary and contradicts flatly the findings of Mr. Day.

"Beside the non-shatterability of the glass, Day argues against the mechanical construction

PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
REL—Relieved from present duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRC—Report to Riverside Field, Riverside, Cal.
RRV—Report to Richmond Aviation School, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
TFT—Report to Taliaferro Field, Fort Worth, Texas. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WFO—Report to Wilbur Wright Field, Fairfield, Ohio.

Note 1—Report to Camp MacArthur, Waco, Tex.
Note 2—Report to Chandler Field, Essington, Pa.
Note 3—Report to Engine and Plane Repair Depot No. 2 Speedway, Ind.
Note 4—Report to Camp Hancock, Augusta, Ga.
Note 5—Report to Army Balloon School, Camp John Wise, San Antonio, Tex.
Note 6—Report to Hoboken, N. J.
Note 7—Report to Chicago, Ill., for duty with Board of Officers.
Note 8—Report to priorities committee, Council of National Defense.
Note 9—Report to Dayton, Ohio.
Note 10—Report to Aviation Repair Depot No. 1, Dallas, Tex.
Note 11—Proceed to Austin, Tex.
Note 12—Report to district manager of equipment, Curtiss Aeroplane & Motor Co., Buffalo, N. Y.
Note 13—Report to Minneapolis, Minn.
Note 14—Report to department aeronautical officer, Eastern Department, New York City.
Note 15—Proceed to Los Angeles, Cal.
Note 16—Report to Capt. James J. Newman, Dayton, O.
Note 17—Report to Lieut Col. William N Hensley, Arcadia, Baldwin race tracks, Los Angeles, Cal.
Note 18—Report to Post Field, Dallas, Texas
Note 19—Report to Aviation Field, West Point, Miss.
Note 20—Report to School for Radio Mechanics, Texas Agricultural and Mechanical College, College Station, Tex.
Note 21—Declined appointment, preferring previous commission.
Note 22—Proceed to Washington, D. C., and then to Wichita Falls, Tex.
Note 23—Proceed to San Francisco, Cal., for duty with Board of Officers.
Note 24—Report to Fort Monroe, Va.
Note 25—Report to Repair Depot, Indianapolis, Ind.
Note 26—Report to commanding general, Western Dept., San Francisco, Cal.

EVERY MILITARY AVIATOR OUGHT TO KNOW WHAT HIS OWN AND THE ENEMY'S MACHINE CAN DO AND HOW THEY LOOK

By HENRY WOODHOUSE

Author of the "Text-book on Naval Aeronautics", "Text-book on Military Aeronautics", etc.

IN the last two issues the writer pointed out that the Allied Government found it necessary to teach their aviators and students all about their own machines, and as much as possible about the enemy's machines, particularly their appearance. As a basic principle, the aviator is taught that what does not look like one of the Allied machines must be an enemy machine. Therefore, every effort should be made to bring it down.

The anti-aircraft forces are taught the same thing, and that knowledge of the features of the different types of aeroplans is one of the prime factors in making the anti-aircraft forces efficient.

Lacking that knowledge, both the Allied air forces as well as the anti-aircraft defenses, get confused and permit the enemy to get temporary advantages, which cost the lives of Allied aviators, as well as of the population of the cities which are raided—without mentioning the strategic advantages which the enemy gains through gathering information or surprising the Allies.

Besides teaching military aviators to know their own and the enemy's machines, what they can do and how they look, the Allied authorities also found it advisable to have continuous progressive changes in their types of aeroplanes.

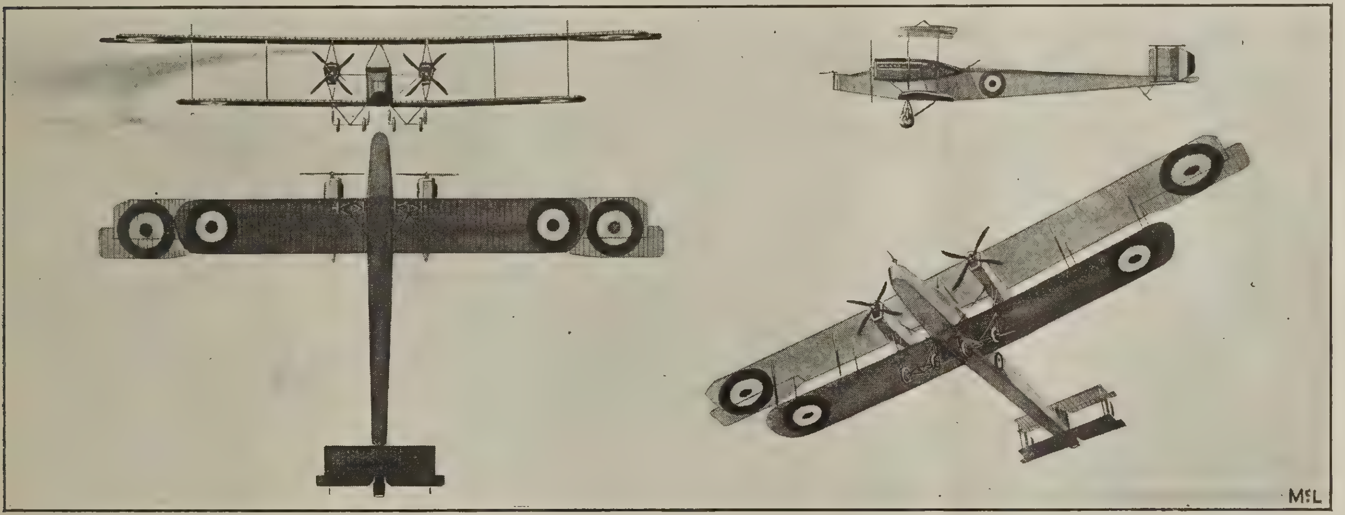
It was found that German aviators had a certain amount of fear for a new type of aeroplane, because they did not know what it could do and past experience had taught them to beware of appearance. As a member of the Lafayette Escadrille put it: "The Boche was never so surprised as when he attacked a certain type of machine which looked like a two-seater, and got fired on by the third passenger, who was an extra gunner, well equipped with twin Lewises."

The policy of keeping the enemy "guessing" is good strategy—so long as it does not interfere seriously with production. It can be applied especially in the smaller types of machines used to maintain the supremacy in the air during the daytime on the fronts. It has little value in so far as the large bombing machines used for night bombing are concerned, because the night aeroplanes cannot be seen. It may be deducted from the types of German machines captured that the Germans are also following this policy. They keep up a continuous progressive change of types, adopting the good points of captured Allied machines, adding other points which are suggested by the progress of the science.

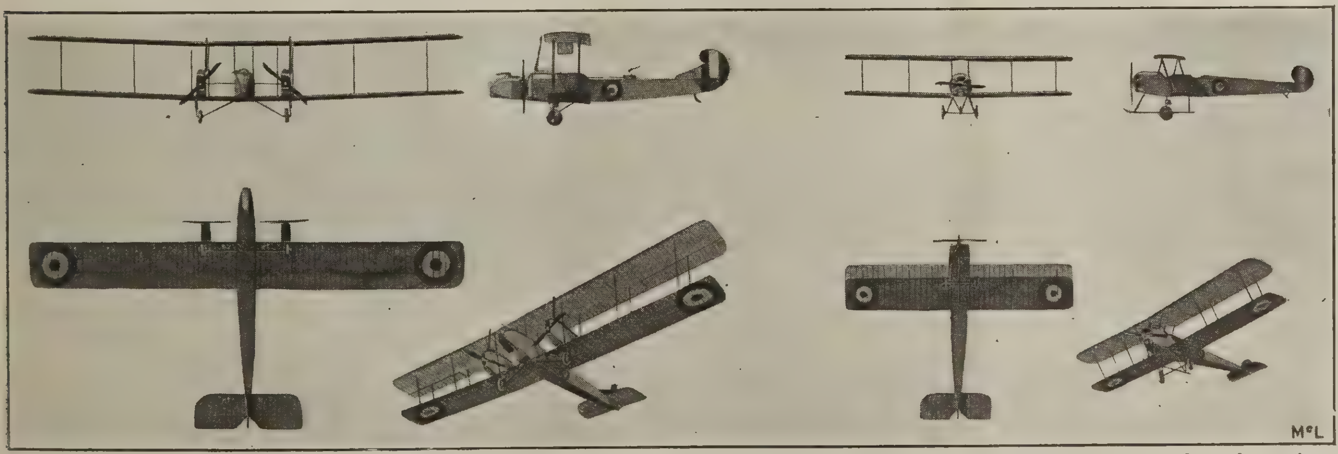
The Gothas followed the capture of the Handley-Page bomber, and now the dispatches advise that the Germans are building larger machines equipped with four motors.

Some of the smaller machines look very much like the French and British machines and it would be hard to recognize one from the other, were it not for the iron cross on the planes. This similarity in characteristics has necessitated closer study of German types and how they look.

Aeroplanes to follow in succeeding issues, in connection with the identifications of military aeroplanes: Pomilio, S. V. A. and others.



Handley Page (British) Twin-engine bombing biplane. One of the largest machines built. It is equipped with two 12 cylinder Rolls-Royce engines of 280 H.P. each. It holds all world's records for large aeroplanes carrying from one (1) to twenty-one (21) passengers. Its wing span is 98 feet. Three Lewis Guns are mounted, two forward and one at the rear. It is identified by its biplane tail, the motor nacelles mounted between the planes, the large overhang of the upper plane and the balanced ailerons. The undercarriage is composed of four shock-absorbing wheels and a small tail skid. The planes are not swept back (as in the German Gotha aeroplane). The Handley Page is a tractor with four-bladed propellers, while the Gotha is a pusher having two-bladed propellers. The engines on the Handley Page are situated entirely forward of the interplane struts, with a fuel compartment aft, but the Gotha's engines are situated between the planes, with portions of the trailing edges cut away for the movement of the propeller.



Avro (A. V. Roe & Co., Ltd.) (British.) The Avro machines have an equal upper and lower wing span. In the twin motored machine the engines are carried on the lower plane, with exhaust stacks running up over the upper plane. Sunbeam, Green or Rolls-Royce vertical engine are used. The landing gear is made up of steel tubing with a wheel located beneath each of the two engines. Two machine guns are mounted on revolving gun rings. The two-seater Avro has highly staggered wings and a slight dihedral. The landing gear is characteristic; the long central skid is located between the wheels, supporting V struts at either end. The rudder is of the balanced "comma" type. There is no vertical fin. A rotary 100 H.P. Gnome or a Le Rhone engine is used.

THE C. IV RUMPLER BIPLANE

THE Rumpler biplane described below belongs to the "C" class of enemy aeroplanes. That is to say, it is a general utility machine, and is perhaps the best in its class. It is chiefly of interest on account of its great speed, which is equal to that of a chaser single-seater, and also on account of its high "ceiling" (6.500 metres). This capacity for flying at great altitudes has led the German aviation services to employ a special respirator adopted recently. The climb of the Rumpler C. IV is also very good (5,000 metres in 35 minutes).

General Specifications

Span, upper plane	12.60	Metres
Span, lower plane	12.10	Metres
Chord, upper plane	1.70	Metres
Chord, lower plane	1.30	Metres
Area, upper plane	20	Sq. Metres
Area, lower plane	13.50	Sq. Metres
Gap between planes	1.85	Metres
Stagger	0.60	Metres
Overall length	8.40	Metres
Overall height	3.25	Metres
Engine, Mercédès	260	H. P.
or Maybach	250	H. P.
Climb in 35 minutes	5,000	Metres

Wings

Both upper and lower wings are swept back 3 degrees. There is a dihedral angle of 2 degrees and the wings are staggered forward 0.60 metres. The trailing edge, contrary to usual German practice, is rigid. The ribs, which are made of three-ply wood, pierced for lightness, are spaced 0.30 metres apart. Their angle of incidence is uniform and is equal to 5 degrees.

In plan the upper wings are of trapezoidal form, with rounded angles. Above the fuselage the trailing edge is cut out as shown in the illustrations. The maximum chord is 1.70 m. In each of the upper wings there are 19 main ribs, and five compression struts of steel tubes. The ailerons are of the tapering type, their chord varying from 0.50 to 0.65 m. The lower wings, as in so many other German machines, have rounded wing tips. As the radius of the arc forming the rear edge is longer than that of the front, the wing tip somewhat resemble that of a propeller blade. Each of the lower wings has 17 main ribs, and four steel tube compression struts.

The interplane struts, of which there are two pairs on each side of the fuselage, are oblique. In section, the inner front struts measure 0.105 m., and the rear strut 0.130 m., while the outer front strut measures 0.090 m. and the rear outer strut 0.085 m. The gap between the wings is 1.85 m., and the total lifting surface is 33.5 square metres, of which the upper wing is 20 square metres and the lower wing 13.5.

Tail

The tail plane, which is not adjustable, is not so deep as in previous types. In plan, the leading edge of the tail plane is approximately a semi-circle. This tail plane is supported on each side by struts attached at their other end to the bottom rail of the fuselage. Two other struts brace the tail plane to the vertical fin. The struts under the tail plane are provided with a series of sharp-edged metal points. It appears probable that the object of these is to prevent the landing crew, when wheeling the machine about, from catching hold of these struts, thus possibly bending them. The elevator is in two parts, each of which is partly balanced by a triangular forward projection. The rudder, which is built up of metal tubes, is of the usual type, and the control cables pass inside the fuselage, guided at points through small wooden tubes.

Fuselage

The construction of the fuselage is of the current type, with four longerons and struts and cross members, braced by piano wire. Front and rear are covered with three-ply wood, and the middle with fabric. The propeller (a Heine) has a diameter of 3.17 m. As on all other German machines, the propeller boss is enclosed in a "spinner."

Engine

The motor fitted on the Rumpler is either a 260 h. p. Mercédès or a 250 h. p. Maybach, both having six vertical cylinders.

When the Mercédès is fitted, it is slightly tilted to the right, in order to allow the induction pipes to pass between the legs of the cabane. With the Maybach, which offers less encumbrance, this arrangement is not necessary. The motor is supplied with fuel from two tanks. The main one (about 220 litres) is placed under the seat of the pilot, the second, the service tank (about 70 litres), is placed at the back of the pilot between him and the gun ring in the gunner's cockpit. The quantity of fuel carried allows of a flight of four hours' duration. The covering over the engine leaves the top of the cylinders exposed, and encloses a Spandau machine gun operated by the motor.

The exhaust pipes run from the six cylinders to a common chimney, curving upwards and backwards. The chimney itself is divided, about half way up, into three branches, probably in order to obtain a certain amount of silencing effect. As in previous models, the radiator, which is semi-circular in shape, is placed on the front legs of the cabane. In front of it is a series of small slats, which can be moved so as to be either parallel to or at right angles to the direction of flight. This is, of course, done in order to make it possible for the pilot to adjust the cooling according to the altitude at which he is flying.

Behind the motor is the pilot's cockpit, and behind him again that of the gunner. Supported on a gun ring in the rear cockpit is a Parabellum machine gun. Pilot and gunner are very close together. In the gunner's cockpit there is a bomb rack of the usual type, carrying four bombs. An opening in the floor permits of taking photographs, and the machine carries a wireless set. The landing chassis is of the V type, with rubber shock absorbers. There is no brake fitted on this machine. An external drift cable runs from the nose of the fuselage to the foot of the inner front interplane strut.—*Courtesy of L'Aerophile.*

INTERNATIONAL AIRCRAFT STANDARDS

Adopted by the International Aircraft Board

(Continued from January number)

The International Aircraft Standards Board, of the Advisory Commission of the Council of National Defense has formulated the following specifications in addition to those printed in our 1083 issue

Specifications for Square and Round Bevel Washers
(4P5 December 1917)

General.—1. The general specifications, 1G1, shall form, according to their applicability, a part of these specifications.

Use.—2. These washers are to be used on bolts (I. A. S. B. specification 4P3).

Material.—3. The washers shall be machined from cold-rolled or drawn steel (I. A. S. B. specification 3S20).

Manufacturer.—4. The washers may be cut by shearing if this can be done without distorting the surface. They shall be cyanide hardened. The washers shall be copper-plated in a cyanide bath and then nickel plated; the coating shall not exceed 0.001 inch (0.0254 mm.) in thickness.

Workmanship and Finish.—5, Both sides must be flat and free from bars.

Physical Properties and Tests.—6. Washers selected for the bend test shall be firmly clamped in a square-nose vise and bent through an angle of 30 degrees. They shall withstand this bending without cracking. One of every 250 washers shall be subjected to the bend test.

Dimensions and Tolerances.—7. The washers shall be of the form shown in figures 1 and 2 and shall conform to the dimensions within the tolerances given in following table. The values represent the finished dimensions after copper and nickel plating.

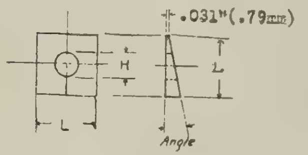

Fig. 1.—Square washer.

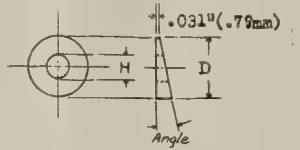

Fig. 2.—Round washer.

Delivery, Packing, and Shipping.—8. The washers shall be delivered in boxes of gross weight not exceeding 50 pounds (22.7 kg.). The lots of individual sizes shall be packed in strong manila envelopes or cartons.

Dimensions and tolerances for bevel washers.

[Values of angle are 6, 12, 24, or 36 degrees for all sizes.]

Specifications for Plain, Ball, and Castle Hexagon Nuts for Aircraft
(4P4 December 1917)

General.—1. The general specifications, 1G1, shall form, according to their applicability, a part of these specifications.

Use.—2. These nuts are to be used on bolts (I. A. S. B. specification 4P3).

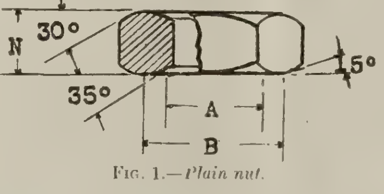

Fig. 1.—*Plain nut.*

Note—Thread chamber to be omitted on sizes smaller than 0.250 inch diameter.

Material.—3. The nuts shall be machined from cold-rolled or drawn steel, I. A. S. B. specification 3S20.

Manufacture.—4. The nuts shall be cyanide hardened. The nuts shall be copper-plated in a cyanide bath and then nickel-plated; the coating shall not exceed 0.001 inch (0.0254 mm.).

Workmanship and Finish.—5. The inside face shall be flat and free from burrs.

Physical Properties and Tests.—6. Nuts shall withstand having inside diameter increased 25 per cent by drifting without cracking. One per cent of each size of all nuts shall be subjected to the drift test.

Dimensions and Tolerances.—7. The nuts shall be of the form shown in figures 1, 2, and 3 and shall conform to the dimensions within the tolerances given in Tables 1, 2, and 3. The values represent the finished dimensions after copper and nickel plating.

Table 1.—*Dimensions and tolerances for plain nuts.*

Delivery, Packing, and Shipping.—8. The nuts shall be delivered in boxes of gross weight not exceeding 50 pounds (22.7 kg.). The lots of individual sizes shall be packed in strong manila envelopes or cartons.

Specifications for Construction of Aeroplane Propellers
(4E1 February 1918)

General.—1. The general specifications, 1G1, shall form, according to their applicability a part of these specifications.

Materials.—2. (*a*) *Wood.*—Woods for the manufacture of propellers for motors of more than 150 horsepower, or more than 1,600 revolutions per minute, are to be black walnut, true mahogany, or quarter-sawed white oak.

For machines under 150 horsepower and 1,600 revolutions per minute, will also be allowed the use of West African mahogany, cherry, and birch. In any case, the manufacturer is not allowed to use a different material from that specified in the design without permission of the purchaser.

Thickness of the boards shall be 0.75 to 1.0 inch, finished.

(*b*) The laminations of the propellers being of irregular shape, imperfections are allowable on edges and parts of boards that will be cut away in the shaping of the propellers, but the stock that goes into the propeller must be straight grain, free from curls, burls, and spiral grain, without knots, checks, dry rot, shakes, dote, or other imperfections, in entire accordance with the I. A. S. B. specifications Nos. 2W3-8 for the lumber.

Sapwood is not permitted in the finished blade, and is not allowed to extend in boss more than 0.75 inch from the edge of the boss, and must in that case be sound.

(*c*) The physical properties of the wood shall be as specified in the I. A. S. B. specification No. 3W1.

(*d*) Stock shall be dried to a moisture content of 7 per cent by methods given in the I. A. S. B. specification No. 3W2.

(*e*) The *glue* used shall conform to I. A. S. B. specification No. 2V2.

(*f*) Materials used for the *sheathing* of propellers for sea planes may be the following:

(1) Sheet copper in conformity to I. A. S. B. specification 3N8.
(2) Monel metal sheet in conformity to I. A. S. B. specification 3N21.
(3) Linen in conformity to I. A. S. B. specification 2F3.
(4) Cotton fabric in conformity to I. A. S. B. specification 2F4.

(*g*) The *spar varnish* used shall conform to I. A. S. B. specification 2V1; the *filler*, to I. A. S. B. specification 2V2. The priming varnish shall be made by dilution of spar varnish with about 2 parts of turpentine.

Manufacture.—3. (*a*) Each board shall be sawed and planed in accordance with blue prints. After planing they shall be glued promptly to avoid absorption of moisture, and great care must be taken to keep the wood under uniform conditions of temperature and humidity during all the operations.

(*b*) Boards shall be balanced before gluing, and heavy ends alternated so as to minimize the effect of variation in the density of the material.

(*c*) The boards shall be sawed for gluing in such a way that the grain follows the lamination of the propeller, avoiding any cross grain. At the same time, the boards shall be so arranged that the grain comes out on the edge, avoiding any flat grain.

(*d*) The practice of gluing edge pieces onto the boards in order to fill out at the boss is forbidden, unless special permission is given by the purchaser. In case such permission is given, the lamination on both ides of the boss widener must be of the full width of the boss; that is, no two laminations which have wideners glued to them shall be adjacent. Both the lamination and the boss widener shall be corrugated at the joint to increase the gluing surface. No splice or "dutchman" shall be permitted on the blade of the propeller. Defective joints shall not be filled with glue. The practice of gluing a thin strip of veneer to the blades will not be allowed.

(*e*) The glue room must be kept at a temperature of 90° to 100° F. (32° to 38° C.), and an average pressure in gluing of 150 pounds per square inch (0.11 kg./mm.^{2}) shall be maintained. Care shall be taken to insure an even pressure on all the parts of the glued surface for not less than 10 hours or longer, at the option of the purchaser. The pressure in the gluing process must not be removed before the expiration of 8 hours after it is completed. This period may be increased at the option of the purchaser.

(*f*) The propeller shall stand at least two days after gluing, nor shall it be finished in less than two weeks after roughing out.

(*g*) The surface of the propeller shall be smoothly sandpapered before the filler is applied, and the curvature shall be true and smooth throughout the length of the blade. Irregularities of contour are not permissible.

Tolerances.—4. (*a*) Propellers shall be inspected for pitch angle, alignment, blade form, and shape of section, as soon as they are finished by the manufacturer and shall come within the following tolerance limits:

	Portion of blades more than 50 per cent radius from axis.	Portion of blades less than 50 per cent radius from axis.
Alignment within.....	0.0625 inch...........	0.0625 inch.
Error in fit of templets	0.01 × width of blade..	0.02 × width of blade.
Width of blade........	0.075 × width of blade.	0.01 × width of blade.
Thickness of section..	0.0625 inch...........	0.125 inch.

For the inner half of the blade length the deviation from the specified pitch angle shall not exceed ± 1.0° at any station, and the difference between the pitch angles at corresponding stations on opposite blades must not differ by more than 1.0°. For the outer half of the blade length the average deviation shall not exceed ±0.3°, the maximum deviation shall not exceed ±0.5°, and the difference between corresponding opposite averages and maximum shall not exceed 0.3° and 0.5°, respectively.

(*b*) The diameter shall conform to the drawings within plus or minus 0.125 inch. The inspector may accept propellers when the diameter is 0.50 inch under specified dimensions, providing not more than 1 propeller in 10 is more than 0.125 inch under the specified diameter.

(*c*) Blades on the same propeller shall be alike within the limits given above. For example, the thickness of the blade may be 0.0625 inch greater or less than specified, but two blades on the same propeller shall not differ in thickness by more than 0.0625 inch.

(*d*) Propellers shall be inspected for alignment at the time of shipment and shall track within 0.0625. If the propeller is not over 0.315 inch out of track, it is permissible to correct the alignment by scraping the wood in the boss.

Sheathing of Propeller with Fabric.—5. (*a*) Before application the fabric shall be scrubbed thoroughly with hot water and soda, and after rinsing allowed to soak in hot water for four hours in order to remove all sizing from the cloth.

(*b*) The process shall be repeated until all the sizing is removed. The cloth shall be dried and applied to the blade in the glue room, with a standard temperature of 100° F.

(*c*) The blades shall be coated evenly with glue, and the cloth applied and ironed smooth, preferably with an electric iron.

(*d*) Twenty-four hours after gluing the fabric shall be given four coats of acetate dope, followed by two coats of varnish or enamel which conforms to I. A. S. B. specifications No. 2V1.

Sheathing of Propellers with Copper or Naval Brass.—6. (*a*) Metal sheathing shall be set in flush with the blade. Rivets of the same material as the sheathing shall be spaced over the area of the sheathing. They shall be applied in such a way as to fit tightly without splitting the wood and shall be applied alternately from the face and the back. The rivets shall then be headed and filed to form a smooth surface. No rivets shall be driven closer than 1 inch from the propeller edge, except at the edge of the metal or in very small blades.

(*b*) A row of rivets about 0.625 inch apart shall be spaced along the edge of the sheathing.

(*c*) The rivets shall not exceed 0.085 inch in diameter and shall show a breaking load of at least 130 pounds (58.9 kg.) at the riveted end and 180 pounds (81.5 kg.) at the head end. The working stress due to centrifugal force shall not exceed 4,266 pounds per square inch (3 kg./mm.^{2}).

(*d*) Sheathing shall be formed to the exact shape of the blade before any rivets are placed.

(*e*) The rivets shall be applied in such a way that they do not follow the line of the grain.

(*f*) When the work is complete the tip shall fit snugly against the wood. Buckling or lifting of the metal shall be considered ground for rejection.

(*g*) Sheathing shall be perforated at the extreme tip by four holes 0.0625 to 0.0938 inch in diameter, to allow the moisture to be removed.

Finishing of Propellers.—7. Propellers shall be finished by the application of 1 coat filler, 2 coats priming varnish, and 3 coats of spar varnish. Each coat should be allowed sufficient time to dry before the application of the next coat.

Balancing of Propellers.—8. (*a*) The propellers shall be tested for balance after the shaping, and after each subsequent operation which effects the balance. For this test the propeller shall be mounted so that it can turn on a horizontal axis, and the sensitiveness of the mounting must be such that it will move at the application of 1 gram (equal 0.036 ounce) at a distance of 2 feet (61 cm.) from the axis.

(*b*) The balancing shall be done in a room free from air currents.

(*c*) The propeller when completed shall stand on the balancing machine in any position without persistent motion in any direction.

Testing of Propellers.—9 (*a*) One propeller of each new design shall be tested by running for at least 10 hours at rated speed on the engines for which it was designed.

(*b*) A centrifugal test of at least one hour duration shall be run at a speed of 10 per cent in excess of the rated speed. This test applies to one propeller of each new or of each unconventional design and to propellers made by inexperienced builders.

(*c*) The deflection of the tip in the axial direction shall not exceed 0.75 inch when the propeller is turning in free air at the rated speed unless greater deflection is an intended feature of the design. This requirement applies to propellers having a diameter of less than 10 feet (3.05 m.).

(*d*) Such additional tests as may be desired shall be stipulated for propellers of untried materials or of radical design, or larger than 10 feet.

HUBBING OF PROPELLERS.—10. (*a*) The large boss hole shall be bored before roughing and shaping in order to insure perfect alignment.

(*b*) The fit of the hub in the large hole shall be neat and close, and the metal flange shall not show perceptible shake. The fit of the bolts in the wood shall be as tight as possible without danger of splitting the wood.

MARKING OF PROPELLERS.—11. (*a*) The propellers shall be stamped in such a position on the boss as to be legible after the placing of the metal flange, with the following information: (1) Pitch, (2) diameter, (3) safe revolutions per minute, (4) whether right or left hand, and (5) serial number.

(*b*) On the blade shall be the manufacturer's trade-mark or name. (4E2, February, 1918.)

Specifications for Valve Forgings
(3S38 January 1918)

GENERAL.—1. The general specification. 1G1, shall form, according to their applicability, a part of these specifications.

MATERIAL.—2. The steel from which these forgings are made shall be chosen from the I.A. S. B. standard steels listed below. The composition chosen shall be stated by the manufacturer or contractor.

For exhaust valves, steel W60, W60*a*, or 51230 shall be used.

For inlet valves, steel W60*b*, X3340, or X3440 may be used and shall conform to the requirements of specification 3S3.

MANUFACTURE.—3. The forgings shall be annealed before machining or heat treating.

WORKMANSHIP AND FINISH.—4. (*a*) The forgings must be uniform in quality, free from pipes, laps, cracks, twists, and seams, and must have a workmanlike finish.

(*b*) A forging may be rejected at any time because of injurious defects or faults which are revealed by manufacturing operations, notwithstanding that it has previously passed inspection. Such rejected forgings shall be returned to the manufacturer at his expense. This clause shall not apply to forgings fabricated after export.

PHYSICAL PROPERTIES AND TESTS.—5. The forgings shall be capable of developing the following physical properties when heat treated:

(*a*) Forgings from steels W60 or W60*a* shall show the following hardness:

Brinel Hardness number	320 to 370
Shore scleroscope hardness number	55 to 65

TENSILE STRENGTH

	Forgings from steel 51230.		Forgings from steel W60*b*, X3340, or X3440	
	Pounds per square inch.	Kilograms per square millimeter.	Pounds per square inch.	Kilograms per square millimeter.
Minimum tensile strength	90,000	63.27	225,000	158.18
Minimum yield point	67,500	47.45	180,000	126.54
Minimum elongation in 2 inches (50.8 mm.)	18 per cent.		30 per cent.	
Minimum reduction of area	9 per cent.		50 per cent.	

Brinell Hardness Test.—(*c*) The Brinell hardness test shall be made after the tensile test has been met. The procedure shall be as follows: Hardness tests shall be made on the forgings selected for the tensil tests and must agree within 3 per cent. The hardness values of other forgings in the same lot must agree with the average of the values so obtained within 3 per cent.

SELECTION OF TEST SPECIMENS.—6. (*a*) Two per cent of the forgings shall be taken for the tensile test.

(*b*) A hardness test may be required on each forging offered. At least 25 per cent of the pieces in each lot shall be tested for hardness.

(*c*) All forgings in a lot shall be heat treated at the same time, and if possible shall be from the same heat of steel.

DIMENSIONS AND TOLERANCES.—7. The forgings shall conform to the dimensions on the drawings within the tolerances specified. Surfaces which are to be machined shall admit of finishing to the required dimensions without leaving trace of original surface.

PACKING, SHIPPING, AND DELIVERY.—8. The forgings shall be boxed for shipment; the gross weight of individual boxes must not exceed 220 pounds (100 kg.) gross weight.

Chemical composition of steels.

NICKEL-CHROMIUM STEELS.

Number.	Carbon.	Manganese.	Phosphorus, maximum.	Sulphur, maximum.	Nickel.	Chromium.
X3340	0.35-0.45	0.45-0.75	0.040	0.045	2.75-3.25	0.70-0.95
X3440	.35- .45	.30- .60	.040	.045	4.00-5.00	1.00-1.50

CHROMIUM STEEL.

Number.	Carbon.	Manganese, maximum.	Phosphorus, maximum.	Sulphur, maximum.	Nickel.	Chromium.
51230	0.20-0.40	0.50	0.035	0,035	None.	11.50-14.00

TUNGSTEN STEELS.

Number.	Carbon.	Manganese, maximum.	Phosphorus, maximum.	Sulphur, maximum.	Chromium.	Tungsten.
W60	0.50-0.70	0.30	0.035	0.035	3.00-4.00	13.00-15 00
W60*a*	.50- .70	.30	.035	.035	3.00-4.00	16.00-18.00
W60*b*	.50- .70	.30	.035	.035	.50-1.00	1.50- 2.00

GENERAL.—1. The general specifications 1G1 shall form, according to their applicability, a part of these specifications.

USE.—2. These tubes are suitable for aeroplane axles and structural members.

MATERIAL.—3. The material for these tubes shall be chosen from the I. A. S. B. standard steels listed below.

MANUFACTURE.—4. (*a*) The tubes shall be cold drawn and shall be furnished heat treated.

Heat Treatment.—(*b*) The tubes shall be heat treated to meet the physical properties specified. The quenching shall be done in oil. Tubes which fail to meet the physical tests may, at the option of the purchaser, be reheat treated.

(*c*) Any tube may be rejected at any time because of injurious defects or faults in the steel which are revealed by manufacturing operations, notwithstanding that it has previously passed inspection. Such rejected tubes shall be returned to the manufacturer at the latter's expense. This clause shall not apply to materials fabricated after export.

WORKMANSHIP AND FINISH.—5. The tubes are to be smooth, of the section specified, and within the permissible tolerances as to wall thickness; of uniform diameter, free from scale, dirt, specks, longitudinal seams, laminations, grooves, and blisters, both internally and externally.

PHYSICAL PROPERTIES AND TESTS.—6. The tubes shall have the following physical properties:

Tensile Test.—(*a*)

	Pounds per square inch.	Kilograms Per square millimeter.
Minimum tensile strength	200,000	140.6
Minimum elongation in 2 in. (50.8 mm.)	5 per cent.	
Minimum elongation in 4 in. (101.6 mm.)	3 per cent.	

Bend Test.—(*b*) Each axle tube shall be supported as shown in Fig. 1 and a load applied near the unsupported end which will develop a tensile stress of 185,000 pounds per square inch (130.0 kg. per sq. mm.) in the highest stressed fibers of the tube. (See formula on p. 3.) The load shall be applied in two equal increments. After the first the deflection of the tube at *B* shall be measured. The second increment shall then be applied for at least five seconds, and removed, and the deflection at *B* again measured. In case the deflection has increased more than 0.0625 inch (1.59 mm.) the tube shall be rejected.

SELECTION OF TEST SPECIMENS.—7. *Tensile Test Specimens.*—(*a*) One tube for the tensile test shall be selected at random from each lot of 100 tubes or less. In case the net sectional area of the tubing exceeds 0.85 square inch (548.4 sq. mm.), two standard test specimens may be machined from the tube before heat treatment. These specimens shall then be heat treated with the lot of tubes they represent, and must show the physical properties specified.

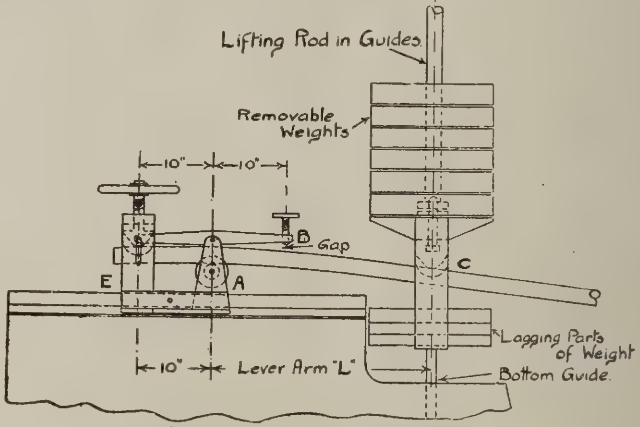

FIGURE 1.—*Diagram of axle-testing apparatus.*

Bend Test Specimens.—(*b*) One end of each tube shall be subjected to the bend test, and one tube in ten shall be tested at both ends.

DIMENSIONS AND TOLERANCES.—8. (*a*) The following tolerances will be allowed on the outside diameter of tubes:

Tubes 1.5 inches (38.1 mm.) diameter and under	0.003 inch (0.08 mm.)
Tubes over 1.5 inches (38.1 mm.) diameter	0.005 inch (0.13 mm.)

(*b*) The variation in wall thickness of tubes may be 10 per cent of the dimensions specified.

(*c*) In no part of any tub shall the departure from straightness exceed 1 in 600.

(*d*) Tubes shall be straightened before heat treatment. After heat treatment the tubes must not be restraightened until the bend test has been applied.

DELIVERY, SHIPPING, AND PACKING.—9. The tubes shall be well oiled and delivered in boxes not exceeding 220 pounds (100 kg.) gross weight.

Chemical compositions of standard alloy steels.

NICKEL STEELS.

Number.	Carbon.	Manganese.	Phosphorous, maximum.	Sulphur, maximum.	Nickel.
2330	0.25-0.35	0.50-0.80	0.040	0.045	3.25-3.75
2335	.30- .40	.50- .80	.040	.045	3.25-3.75

NICKEL-CHROMIUM STEELS.

Number.	Carbon.	Manganese.	Phosphorous, maximum.	Sulphur, maximum.	Nickel.	Chromium.
3130	0.25-0.35	0.50-0.80	0.040	0.045	1.00-1.50	0.45-0.75
3135	.30- .40	.50- .80	.040	.045	1.00-1.50	.45- .75
3140	.35- .45	.50- .80	.040	.045	1.00-1.50	.45- .75
3230	.25- .35	.30- .60	.040	.045	1.50-2.00	.90-1.25
3240	.35- .45	.30- .60	.040	.045	1.50-2.00	.90-1.25

IUM-VANADIUM STEELS.

Number.	Carbon.	Manganese.	Phosphorous, maximum.	Sulphur, maximum.	Chromium.	Vanadium minimum.
6130..................	0.25-0.35	0.50-0.80	0.040	0.045	0.80-1.10	0.15
6140..................	.35- .45	.50- .80	.040	.045	.80-1.10	.15

The extreme fiber stress shall be calculated from the following formula:

$$S = \frac{32\ WlD}{\pi(D^4 - d^4)}.$$

Where S = extreme fiber stress.
W = the load.
l = distance from support to load.
D = outside diameter of tube.
d = inside diameter of tube.

Specifications for Free Cutting or Screw Machine Brass Bars (3N22)

General.—1. The general specifications, 1G1, shall form, according to their applicability, a part of these specifications.

Use.—2. This material is to be used for screw machine work; it is not suitable for structural parts of aeroplanes and is intended only for use in machine parts not subject to considerable stress.

Material.—3. The bars shall have the following chemical composition:

	Per cent
Copper	60.0 to 63.0
Lead	2.25 to 3.25
Iron, not more than......................	.10
Other impurities, not more than..........	.25
Zinc	Remainder

Manufacture.—4. The brass shall be made from lake or electrolytic copper conforming to I. A. S. B. specification 2N2 and spelter of "C" or "D" grade conforming to I. A. S. B. specification 2N3. No scrap shall be used in the manufacture of these bars other than that produced in the manufacturer's own plants and which is of the same composition as the material specified.

Workmanship and Finish.—5. All bars shall be sound, straight, free from roaks, laps, cracks, twists, seams, and damaged ends, and are to have a workmanlike finish.

Physical Properties and Tests.—6. The bars shall have the following physical properties:

Tensile Test.—(a)

	Minimum tensile strength	
	Pounds per square inch	Kilograms per square millimeter
Bars less than 1 inch in diameter.............	55,000	38.6
Bars from 1 to 2 inches in diameter.........	50,000	35.1
Bars over 2 inches in diameter..............	45,000	31.6

Bend Test.—(b) The bars shall withstand being bent cold through an angle of 120 degrees to a radius equal to the diameter of the rod without cracking. The bend test bar shall be full size up to a diameter of 1.50 inches. Test bars of rods of larger diameter may be machined to a diameter of not less than 1 inch.

Selection of Test Specimens.—7. The bars shall be grouped into lots of not more than 500 pounds if of one-half inch or less in diameter, or into lots of 50 pieces if larger. A tensile-test specimen and a bend-test specimen shall be cut from one bar of each lot.

Dimensions and Tolerances.—8. Bars shall not vary in diameter more than the following amounts:

	Inch
For bars up to and including 0.375 inch in diameter..........	±0.0015
For bars from 0.375 inch up to and including 1 inch in diameter	± .0030
For bars over 1 inch in diameter..................................	± .0050

Delivery, Packing, and Shipping.—9. (a) Bars when ordered to any length shall be furnished in stock lengths unless specifically required that lengths be exact.

(b) Stock lengths will be as follows:
When ordered in 12-foot lengths, no length shall be less than 8 feet.
When ordered in 10-foot lengths, no length shall be less than 6 feet.
When ordered in 8-foot lengths, no length shall be less than 6 feet.
When ordered in 6-foot lengths, no length shall be less than 4 feet.

(c) When ordered to the lengths given above, the weight of lengths less than length ordered shall not exceed 40 per cent of any one shipment.

Specifications for Bronze Castings for Bearings (3N19)

General.—1. The general specifications, 1G1, shall form, according to their applicability, a part of these specifications.

Use.—2. These castings shall be used for small unlined bearings and bushings.

Material.—3. The castings shall have the following chemical composition:

	Per cent
Tin	10 to 11.5
Zinc	2 to 3
Iron, not more than	0.2
Lead, not more than	0.2
Copper.	Remainder

Manufacture.—4. (a) The bronze shall be made from lake or electrolytic copper conforming to I. A. S. B. specification 2N2 and pig tin having a purity of at least 99 per cent.

(b) No scrap shall be used in the manufacture of these castings other than that produced in the manufacturer's own plants and which is of the same composition as the material specified.

Workmanship and Finish.—5. Castings must be homogeneous and free from shrinkage cracks, spongy spots, blowholes, and foreign matter. Any castings developing defects in machining must be replaced by the manufacturer. The full weight of material in the original casting must be returned by the purchaser for each replacement.

Physical Properties and Tests.—6. Bronze castings for bearings shall have the following physical properties:

	Pounds per square inch	Kilogram per square millimeter
Minimum tensile strength..................	35,000	24.6
Minimum yield point.........................	19,000	13.3
Minimum elongation in 2 inches............	9 per cent	

Selection of Test Specimens.—7 (a) The test bars shall be cast to size either from the casting, if the size of the same will permit, or from a separate block. The test bar shall be connected with the casting or block by a 0.125-inch (3.18 mm.) gauge running the entire length of the test bar.

(b) The test bar shall be of such a form that it can be machined to the I. A. S. B. standard test bar. Its total length shall be not less than 6 inches (152 mm.). The diameter of the reduced section shall be approximately 0.57 inch over a length of 2.25 inches.

(c) At least two test bars shall be cast from each heat. Test bars and castings shall have the heat number cast or stamped upon them.

(d) One test shall be made to represent each heat, but in case of a flaw in the test bar or a break outside of the middle third of the gauge length, further tests may be made on extra test pieces, as provided for in the foregoing paragraph.

Dimensions and Tolerances.—8. All castings must be true to pattern; cores must be correctly placed. Surfaces which are to be machined shall admit of finishing to the required dimensions without leaving any trace of the original surface.

Specifications for Aluminum Alloy Tubing (3N17)

General.—1. The general specifications, 1G1, shall form, according to their applicability, a part of these specifications.

Material.—2. The specific gravity of the aluminum alloy of this specification shall not be greater than 2.85.

Manufacture.—3. No scrap shall be used in the manufacture of this tubing other than that produced in the manufacturer's own plants and which is of the same composition as the material specified.

Workmanship and Finish.—4. The tubing shall be straight, clean, smooth, and free from all injurious defects both inside and outside.

Physical Properties.—5. *Tensile Test.*—(a)

	Minimum tensile strength		Minimum yield point		Elongation in 2 inches, per cent
	Pounds per square inch	Kilograms per square millimeter	Pounds per square inch	Kilograms per square millimeter	
Temper 1.....	55,000	38.6	35,000	24.6	12
Temper 2.....	50,000	35.1	25,000	17.6	20

Bend Test.—(b) A section of the tubing of a length approximately equal to the outside diameter of the finished tube shall withstand being flattened into an oval of which the minor interior axis shall not be less than 4 for temper 2, and 6 times for temper 1, the thickness of the wall of the original tube.

Hydrostatic Pressure Test.—(c) Each tube shall be subjected to a hydrostatic pressure which will develop a tensile stress of 7,000 pounds per square inch (4.92 kg./mm.^{2}) in the tube, but in no case shall a test pressure of more than 1,000 pounds per square inch (0.703 kg./mm.^{2}) be required. Each tube must withstand this test without cracks, flaws, leaks, or other defects such as bulging.[a]

[a] The pressure to be applied shall be calculated from the formula

$$P = \frac{7,000T}{R}$$

Where P = the hydrostatic pressure in pounds per square inch.
T = the thickness of the tube wall in inches.
R = the internal radius of the tube.

Selection of Test Specimens.—6. Each bar shall be subjected to a hydrostatic test. A tensile and a bend test specimen shall be taken from each 100 feet of tubing or lot of less than 100 feet.

Dimensions and Tolerances.—7. (a) The following tolerances shall be allowed on aluminum alloy tubing.

Outside diameter.—(b) For tubes less than 2 inches in outside diameter, ±0.003 inch; for tubes from 2 to 3 inches in diameter, ±0.005 inch.

Wall Thickness.—(c) The wall thickness of the tube shall be not less than the specified gauge and shall not be exceeded by more than 0.004 inch for tubes less than 0.008 inch in wall thickness, nor by more than 5 per cent for thicker tubes.

Variation.—(d) The variation in thickness, due to eccentricity of the bore may not exceed ±10 per cent of the specified wall thickness.

Length.—(e) When tubing is ordered in definite lengths, no length furnished shall be less than that specified.

THE USE OF SPRUCE IN AEROPLANE CONSTRUCTION

By J. A. NEWLIN

In Charge Section of Timber Mechanics Forest Products Laboratory,
Forest Service

BECAUSE spruce combines the qualities of lightness, great strength and stiffness per unit weight, and a considerable degree of toughness, it is of great value in the manufacture of aeroplanes where just such qualities are demanded. Wing beams and struts are usually made of spruce, cut in such shapes as will give the greatest strength with the lightest weight.

This paper deals with data obtained by the Forest Products Laboratory of the Forest Service. It gives some general information relative to the species and conditions of growth of spruce, the influence of moisture conditions on aeroplane stock, and the relation of density to moisture content, shrinkage, and strength. As density is recommended as the best criterion of strength properties, methods of determining density, or specific gravity, are included.

Species

Red spruce, Sitka spruce and white spruce are the species upon which data have been obtained, and which are known to be valuable for aeroplane construction. There is no material difference in the strength of these species, and the choice of one over another is based on other properties of the wood, such as clearness, straightness of grain, cost, etc.

Locality of Growth

The red and white spruces are eastern woods having a large range of growth east of the Mississippi and north of the Ohio. The Sitka spruce grows on the west coast, from Washington and Oregon to Alaska. Tests indicate that there is no material difference in Sitka spruce from difference localities. This species attains a much larger size than the eastern varieties, being, in fact, one of the largest North American trees. Conditions of growth, density of the woods, and numerous other influences which will be taken up herein have a direct bearing on the quality of spruce.

Rate of Growth

Very rapid growth spruce is usually productive of inferior material. Experiments show that, other things being equal, spruce shows greater strength with the greater number of annual growth rings, up to about 15 rings per inch. Above that point, there is no noticeable increase or decrease in strength, according to the number of rings. Wood with less than 8 or 10 rings per inch is usually considerably weaker and lighter.

Position in Tree

Very commonly there is a difference in strength in wood taken from near the butt of a tree and that taken from farther up in the trunk, and in most cases the weaker wood comes from the higher portions of the tree. But in the case of spruce the wood shows no difference with height, and, if other factors are equal, wood taken from far up in the trunk of the tree will be as good as that near the butt.

With respect to location in the cross section of the tree, wood immediately surrounding the pith center is usually light and weak, the strength and density increasing with the distance out from the center. The increase in density with distance out from the center, however, is not so marked as the increase in strength.

In trees above medium size, the density and strength do not continue to increase with the diameter.

Heart and Sap

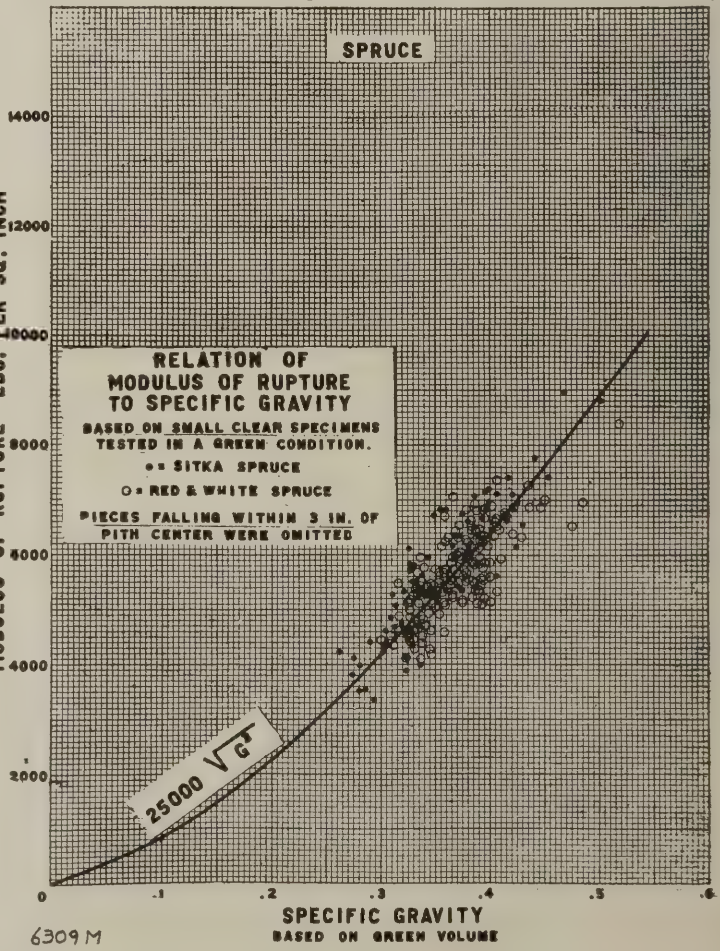
There are no indications of any change in strength due to the transition from the heart to the sapwood in the spruces.

Specific Gravity, or Weight, and Its Relation to Strength

The spruces follow the general law of timber in regard to strength properties and weight; i. e., all the strength values increase as the specific gravity increases. The closeness with which they follow this law, and the relation by which the strength may be estimated if the specific gravity is known, is shown by the two curves for modulus of rupture and maximum crushing strength. Where the oven-dry specific gravity for spruce, based on volue when green, is over .33, or over .36 when based on oven-dry volume, excellent material is obtained,—assuming, of course, that defects such as knots, spiral grain, etc., have been eliminated previously. Clear wood with the above specific gravities would seldom run below 4,500 pounds per square inch in modulus of rupture, or below 2,000 pounds per square inch in maximum crushing strength along the grain when green. Drying to the condition of airplane stock would increase these minimum strength figures to about 8,000 pounds and 4,000 pounds per square inch, respectively.

Variations in Moisture Content of Aeroplane Lumber

Lumber received at the aeroplane factory is of various sizes and conditions of seasoning. The material is used too rapidly to permit of long time storage and air seasoning under favorable conditions. As the lumber is cut into sizes approximately ready for the machine, it is run into conditioning chambers in which the seasoning of the lumber is hastened. A relatively short time elapses after the removal of the material from the conditioning chamber to its manufacture into finished size. Under such conditions there must of necessity be a wide variation in the moisture content of machined material. Some of the factors which influence this moisture content are variations in the original moisture content, position of the specimen in the pile, or conditioning chamber, and the difference in density of individual pieces which cause them to dry at different rates. It is the general observation that, of two pieces of the same species but differing in density, the lighter piece will dry the more rapidly. Observations made by the laboratory at various aeroplane plants would lead to the belief that a variation



6309 M

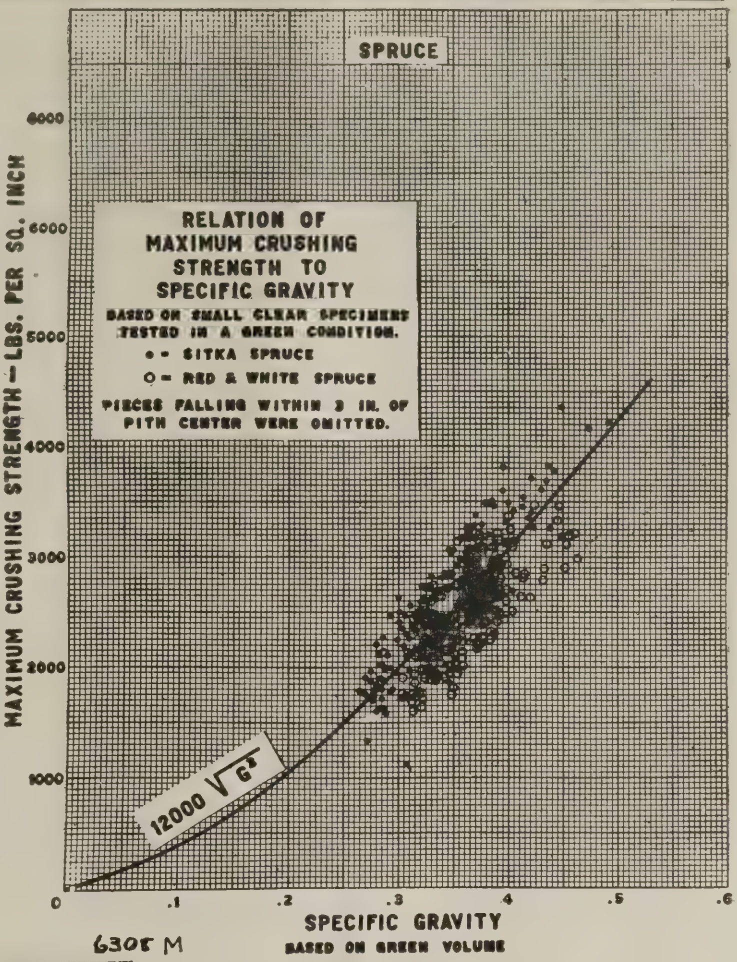
of as much as 10 per cent in the moisture content of the material as it goes through the machines may be expected, although no data on this point are available.

Influence of Changes in Moisture Content After Machining on the Size of the Finished Part

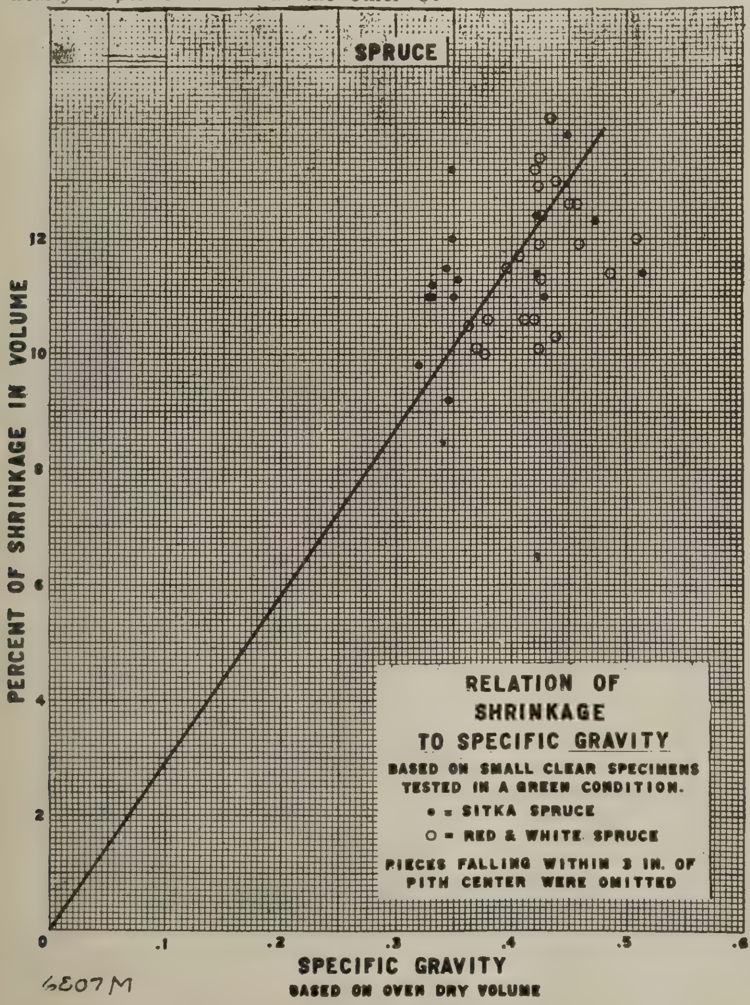
The accompanying chart gives the total shrinkage in volume of spruce from the green condition to the oven-dry condition, or zero moisture. About .6 of this amount would represent the tangential shrinkage and about .4 the radial shrinkage of the specimen.

Good spruce may be assumed to shrink about 12½ per cent from the green to the oven-dry condition. The ultimate moisture content of the airplane stock in service is probably in the neighborhood of 9 per cent moisture. Each change of 1 per cent moisture at about 9 per cent may be assumed to give about one-twentieth of the total shrinkage; that is, a 1 per cent change in moisture content of good spruce would give .6 of 1 per cent change in volume, equivalent to about .35 of 1 per cent in tangential shrinkage and .25 of 1 per cent radial shrinkage.

Were the material allowed to stand for several weeks at approximately the humidity condition of the assembling room before manufacture, it probably would all arrive at about a uniform and suitable moisture content. However, under the forced conditions which exist it is safe to assume that the better pieces of machined timber frequently have at least 5 per cent more moisture than they will ultimately have. This change of 5 per cent moisture which may take between the time of machining the part and its final use would cause a reduction in one dimension of nearly 2 per cent and in the other of nearly 1½ per cent. In a built-up propeller, any such changes in moisture condition of the finished product would certainly tend to split and twist it, since the different laminations containing different percentages of moisture would shrink unequally. This variation of 2 per cent in a single direction could also be produced by differences of humidity between a warm, dry season of weather lasting for two or three weeks as against a moist atmosphere for the same length of time. As may be seen by the diagram, spruce tends to show a greater shrinkage in heavier pieces than in light pieces. Consequently, pieces of low weight which would be considered of low quality would not cause so much trouble from shrinkage as the heavier and stronger pieces.



RELATION OF MAXIMUM CRUSHING STRENGTH TO SPECIFIC GRAVITY
BASED ON SMALL CLEAR SPECIMENS TESTED IN A GREEN CONDITION.
● = SITKA SPRUCE
○ = RED & WHITE SPRUCE
PIECES FALLING WITHIN 3 IN. OF PITH CENTER WERE OMITTED.



RELATION OF SHRINKAGE TO SPECIFIC GRAVITY
BASED ON SMALL CLEAR SPECIMENS TESTED IN A GREEN CONDITION.
● = SITKA SPRUCE
○ = RED & WHITE SPRUCE
PIECES FALLING WITHIN 3 IN. OF PITH CENTER WERE OMITTED

From the foregoing remarks it will be seen that, by throwing out material on account of a very slight under size, except where the dimensions are taken immediately after machining, higher quality pieces are likely to be excluded.

Influence of Changes in Moisture Content Upon Strength

Under the varying conditions of moisture as given above, the random selection of specimens for strength tests is to be discouraged, since the moisture content of the specimen has a tremendous influence on the strength. For example, 1 per cent of moisture causes approximately 5 per cent difference in the crushing strength parallel to the grain. As light pieces may come to a low moisture content and the heavy pieces to a relatively high moisture content at the time of machining, although the ultimate moisture content in service will probably be about the same, specimens taken under such conditions will give abnormally high values for poor material and low values for good material. The tests, therefore, become of practically no value unless corrections are made for moisture.

FOREIGN NEWS

FRANCE

The French official announcement of March 17th reports the following aerial activities:

"On March 16th one German aeroplane was destroyed and four others damaged severely by French aviators. Our bombing squadrons dropped 7,000 kilograms of projectiles on military establishments behind the enemy front."

The night announcement of the 17th concludes as follows:

"On Saturday our pilots destroyed two German aeroplanes. Five other enemy machines fell within the German lines. Information now at hand shows that on March 13th and 15th four German aeroplanes, in addition to those previously reported, were brought down."

Extensive bombing operations are reported in the activities of March 18th, as follows:

"On Sunday three German aeroplanes were destroyed and six others were badly damaged by our pilots. A captive balloon was set on fire by one of our aviators. Furthermore, it has been learned that two other German aeroplanes were brought down on March 15th and 16th. Our bombarding squadrons threw down 6,000 kilograms (6.6 tons) of explosives on Saturday and 5,000 kilograms (5.5 tons) on Sunday on cantonments, other military establishments and railway stations of the enemy.

Successful bombing operations occurred on the 19th, according to the announcement of March 20th:

"Bad weather yesterday impeded aerial operation. Information now at hand shows that the six German aeroplanes and one captive balloon reported as having been damaged on the preceding day in reality were destroyed by our pilots.

"Our bombarding squadrons yesterday and the day before, operating as freely by day as by night, threw down 13,000 kilograms (28,600 pounds) of projectiles on military establishments, aviation grounds and railway stations in the enemy zone. Several explosions and two fires were observed in buildings bombarded."

The French official day report of March 22nd says that "it has been established that on March 5th, Sub-Lieutenant Harbelin brought down his tenth German aeroplane."

The night report of the 22nd says:

"Two German aeroplanes were destroyed and four badly damaged in a series of combats with our air squadron. Three enemy machines were shot down by our special artillery."

The announcement of the 23rd says:

"In the period from March 11 to March 20 twenty-six German aeroplanes and one captive balloon were shot down by our aviators. Nineteen enemy machines were seriously hit and brought down within the enemy lines. On March 22 five German aeroplanes were shot down or gravely damaged by our aerial units.

"On the night of March 22-23 our raiding squadrons dropped 35,200 pounds of projectiles upon establishments, cantonments and railroad terminals in the enemy zone. It was ascertained that the damage done was very great."

GERMANY

In the announcement of March 18th the Germans summarize aerial activity for the month of February, as follows:

"On the whole front the aerial activity was very marked. The French bombed hospital establishments at Le Thour, which were clearly recognizable as such. Yesterday we shot down twenty-two enemy aeroplanes and two captive balloons.

"In February the losses of the enemy aerial forces on the German front amounted to eighteen captive balloons and 138 aeroplanes. Fifty-nine of these aeroplanes fell behind our lines and the remainder beyond the enemy positions. In aerial encounters we lost sixty-one aeroplanes and three captive balloons."

GREAT BRITAIN

Intense aerial activity was described in the War Office statement of March 18th, as follows:

"A good visibility on Sunday enabled our aviators to increase their work in the air. The railway sidings at Somain and hostile rest billets on all parts of the front and three of the enemy's aerodromes were heavily bombed, a total of ten and one-half tons of bombs being dropped. Over one of the aerodromes attacked a fierce encounter took place, as the result of which three hostile aeroplens were destroyed our own suffering no losses.

"During to-day eighteen German machines were downed, eight driven down out of control and an observation balloon destroyed. Four of our machines are missing.

"Our night flying machines dropped five tons of bombs on two hostile aerodromes, one of which was occupied by large bombing machines, and also on a big ammunition dump northeast of St. Quentin and on billets in the neighborhood of Douai and Menin."

The announcement of March 19th reports further intense aerial activity on the part of the British air service, as follows:

"Nine tons of bombs were dropped Monday on enemy rest billets and ammunition dumps and also the Busigny railway station and two aerodromes, one of which was occupied by large bombing machines.

"Aerial fighting was exceedingly intense, encounters occurring between large formations. Nineteen German aeroplanes were destroyed, and nine were driven out of control. Twelve of our machines are missing.

"Six hundred bombs were dropped during the night on two aerodromes used by enemy night flying machines and on ammunition dumps and billets. All our machines returned."

Cloudy weather on March 20th almost prevented aerial activity, says the official report on aviation.

"After dark the weather cleared and hostile aerodromes southwest of Tournal and a large ammunition depot northeast of St. Quentin were bombarded, three hundred bombs being dropped."

British aircraft during the fighting along the front in France on March 22nd:

"The mist over the whole front Thursday morning cleared locally later, but at most places the weather was unsuitable for low flying. The enemy's attacking troops and reinforcements on the battle front offered excellent targets to the pilots of our low flying machines, which poured many thousands of rounds into them, causing innumerable casualties.

"Our bombing machines also attacked these targets, in addition to bombing important railway stations on the battle front, more than one hundred bombs being dropped.

"A great deal of fighting occurred at low altitudes, in which sixteen hostile machines were downed and six driven down out of control. A hostile balloon was destroyed by one of our pilots. One ot the enemy's low flying aeroplanes was shot down in our lines by infantry. Three of our machines are missing.

"During the night, night flying squadrons in the southern area of the front were unable to leave the ground owing to the mist. In the northern area, where the weather was clear, our aeroplanes dropped 3½ tons of bombs on the dockyards at Bruges and 3½ tons of bombs on rest billets northwest of Tournai. All of our machines returned."

The official report on the aerial operations, issued March 24th, says that fifty-four enemy aeroplanes have been brought down.

"The enemy's low flying aeroplanes were most persistent in their attacks on our infantry in the forward areas. Many of these machines were attacked and brought down by our pilots. A total of twenty-nine hostile machines were brought down and twenty-five others were driven down out of control. Two enemy balloons also were destroyed. Nine of our machines are missing.

"Our machines on Saturday carried out another successful raid on factories in Mannheim. Nearly one and a half tons of bombs were dropped, and bursts were seen on a soda factory, the railway and docks.

"Several fires were started, one of which was of great size, with flames reaching to a height of 200 feet and smoke to 5,000 feet. The conflagration was visible for a distance of thirty-five miles."

"The weather Saturday again favored operations, and our aeroplanes were constantly employed in reconnoitring positions of troops, in photography and bombing and in reporting suitable targets for our artillery. Many thousands of rounds were fired by our pilots fom low altitudes on hostile troops massed in villages and in the open continuously throughout the day.

"More than fourteen tons of bombs were dropped on enemy billets, on his high velocity guns and on railroad stations in the battle area."

"Our bombing aeroplanes were attacked by thirty-two hostile machines, and a fierce fight ensued. One of the enemy's aeroplanes was brought down in flames and another was downed, and fell in the centre of Mannheim. Five others were driven down out of control.

"Despite this severe combat and the enemy's heavy anti-aircraft gunfire all our machines returned except two. During the night ten heavy bombs were droppen on an important railway bridge and works at Konz, just south of Treves, in Germany. Eight of these bombs were clearly seen to be bursting among the railway works.

"Nearly two tons of bombs were dropped from low heights on a hostile aerodrome south of Metz. Six bombs were seen to burst among the hangars and to set fire to some of the huts of the aerodrome. All our machines returned.

"From nightfall until early morning our night flying squadrons bombed areas on the battlefront in which hostile troops were concentrated, as well as enemy ammunition dumps and large guns. More than fourteen tons of bombs were again dropped by our machines, two and a half tons of which were loosed on the docks of Bruges. All our machines returned."

The War Office on March 21st issued a statement on operations in Palestine as follows:

"We occupied Beit Rilma and Kefrtut, both east-southeast of Deir Ballett, unopposed. We drove off a counter attack at Deir Ballett and secured Elowsallabeh and the high ground to the westward.

"Airmen dropped 470 bombs on establishments in the vicinity of Elkutrani station. Direct hits were observed on the objectives."

British naval aeroplanes from Dunkirk destroyed five German machines between March 13th and 17th. Five other machines were brought down and two enemy observers were killed. All the British machines returned safely.

"On March 19th a British seaplane patrol, flying in Heligoland Bight, encountered two enemy seaplanes ten miles northeastward of Borkum," says an Admiralty announcement.

"The enemy was engaged and one of his machines was driven down in flames. Our machines returned safely."

ITALY

On March 18th it was announced that:

"Five hostile aeroplanes were brought down by our aviators. Last night a naval airship bombed an enemy aviation ground."

The destruction of seven enemy planes is announced on March 19th:

"Seven enemy aeroplanes were brought down yesterday, two by the Italians, two by the French, and three by the British."

Destruction of enemy aircraft is announced on March 20th:

"Our aviators set fire to two enemy captive balloons at Conegliano and Col Mirano. Two hostile aeroplanes were brought down, one by French aviators at San Giacomo di Veglia and the other by British airmen on the Asiago Plateau."

The announcement of March 22nd reports the following aerial activity:

"On the Asiago Plateau French and Italian aeroplanes brought down an enemy aeroplane. Beyond the Piave the British aviators brought down three enemy aeroplanes and forced another to land. Southward of Motta di Livena a captive balloon was set afire by our artillery.

"Our aircraft dropped bombs on railway lines in the Lagarina Valley," says the announcement of the 23rd.

American aviation students now in Italy will co-operate with Italians in aerial defense, it was announced on March 22nd.

The Davies Glider No. 2

THE following description of Mr. Davies' Glider was sent to "Flight" and is so full of interest and information that we take pleasure in reproducing the article in full:

"My first letter appeared in "Flight" as far back as August, 1911, and gave a description of my first glider. From start to finish it was nothing but a lump of bad luck. Encouragement and local interest was at the time anything but brisk, and not having suitable grounds I decided to take it to pieces and go back to experimenting with models. It was not very long after having come to this decision that I came across a very suitable ground for gliding experiments, and this having caused the flight fever to come on again, I was quite unable to resist the desire to build another, this time a machine of similar dimensions but with constructional details much improved, and so made as to be easily assembled or taken to pieces, strong and yet light.

"Work went on but very slowly, as I built the machine entirely myself. When finished the space occupied was 21 ft. by 6.5 ft., but it was a long time to rig up the machine. Fortunately, however, I was not handicapped for room, so that the tail and outriggers were put together as one, and the cellule braced with the extensions down. On arriving at the flying ground very little had to be done, except putting up the extensions and bolting on the tail outriggers, which are shown.

"The gliding ground was at a distance of 6 miles from the building shed, and the transportation of the machine was undertaken quite on a military basis, the axle and wheels were half turned round on the skids, the tail slung on the extension, and the machine pushed off at top speed. The time the very early morning. We arrived at our destination feeling a little knocked up. The crew with me, which numbered six, worked as happy as if at an aviation meeting, all setting to and helping me to get the machine ready. I had decided from my experience with No. 1 that it would be better to get into the seat rather than risk her on her own. Having done so, a really delightful trip took place, at a height of about 5 ft. only from the ground, being pulled quite 50 yards; the wheels making it possible to get up speed quickly, and acting admirably in every way.

"These towed flights were the most successful, free glides being limited; we never seemed to get sufficiently high to accomplish long free glides, the longest free flight being about 130 ft., but much longer towed flights were made.

"I account for this by reason of the insufficient slope of the ground and the small supporting area, which works out at 1 lb. per sq. ft., which is too heavy. I should strongly advise builders to have a loading only of ¾ lb. sq. ft. rather than a smaller area and consequently heavier loading. It is much better as a test of your manipulatory skill, and avoids also landing at a speed and with a bump that the above machine did. Above all, be most particular with respect to the wind speed.

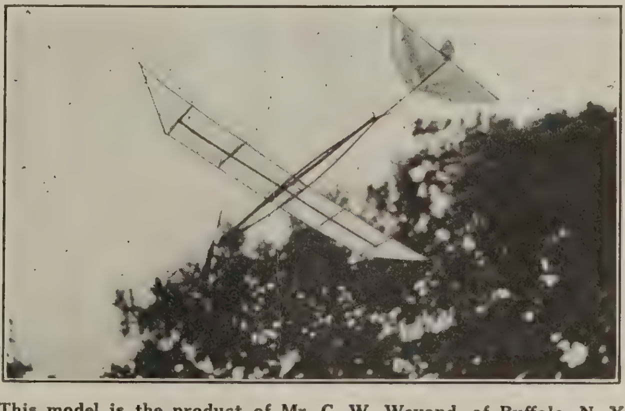
"One particular morning that we shall never forget, we motor cycled over to the ricksheds (the hangar) and found the wind much too high, but the sound of my 'Rudge multi' engine must have woke up some of the people in the neighborhood, who knew quite well that the glider was there, and they must have thought that I had got an aero motor for the machine, for they came simply like a swarm of bees.

"The wind was still too strong, and the people got so very tired of waiting, and not wanting them to lose interest, I decided something should be done. To try a solo flight was madness, so I looked round for a passenger. The machine was wheeled from the shed into the open field, each of the crew at his proper place, a friend of mine (small in build, of course) volunteered to take the place as passenger. This we thought (if anything should be really accomplished) would be quite sensational.

"Before giving and explaining the result, it would be as well perhaps to mention that the angle of the tail plane was very high, thus throwing the centre of pressure further aft and making my position not so dangerous as if placed too far forward (H. Farman fashion); at the same time, this was upsetting theory, as there was no longitudinal dihedral making it safe for myself from a landing point, but stability was so far sacrificed. William Westwood was my passenger, and we sat *very* close together: the crew pulled the machine and off we went, still remaining on the ground, when all of a sudden up we popped and down we came, a most terrible bump, I pushing the passenger off the back, after crawling from under the wreckage; poor Billy was limping, he had cut his leg, so we took him to see the doctor, where a few stitches were inserted. After the doctor had patched up and made good we returned to the glider, and to my surprise the most important part, the four main spars, had broken through after my passenger and I had come through the top plane, and seeing that the *cabanes,* extensions and *ailerons* were smashed as well, I thought the best thing to do was to start afresh rather than patch up.

"As a result of the foregoing experience I strongly advise those who are thinking of building a glider to use bamboo for their spars, outriggers and ribs, as it will bend when receiving a shock, and will not break at that. Built on this principle, and strongly braced with 16 g. piano wire, with a strainer to each diagonal, and to employ 300 sq. ft. of supporting surface, and to experiment in a reasonable wind and slope. [A loading of ¾ lb. per sq. ft. requires a wind of about 20 m.p.h. to soar.

"No doubt readers will not admire the tail outriggers, but I found it answered well, as it is the only tail out of four that I have not smashed; it was also very rigid. The outriggers themselves are sawn down 6 ins., the plate let in pegged and bound with string. The outrigger is continued to the tail strut, where a skid is fitted. The aluminum strut sockets and brackets for *cellule* bracing are bolted to the main spars. The elevating control, consists of a universal joint, wood handle bar bolted to 1¼ in. solid drawn steel tube."



This model is the product of Mr. C. W. Weyand, of Buffalo, N. Y. In a recent test the model rose from the ground and flew over 450 feet at an approximate height of 100 feet. For a tractor not measuring over 14", this is a rather good flight

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

A Student Aviator's Night Before Exam

By James C. Gibson

Once I tho't an aeronaut had naught to do but fly, that sometimes he would drop a bomb and sometimes he would die. I never knew he had to learn each blooming scientific term and appelations technical for every twist and squirm. But, Gee, thru A and B and C and so on to the last the names and parts and stops and starts come shooting thick and fast.

I dream of water jackets now and cooling fins and bores, I study intake valve with the pressure of my snores, I pore o'er head resistance 'till my head cannot resist it, the obturator ring is ringing and I do not dare to twist it. I often wake with concave head from dreaming planet gears—air cool my cheeks to get the churning motion from my ears.

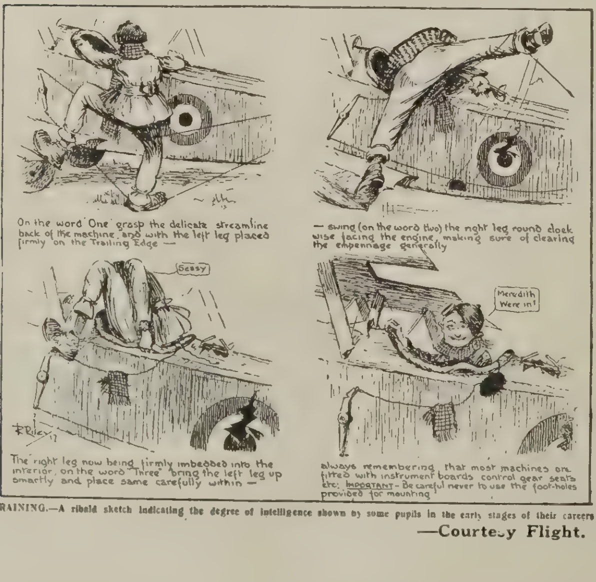
I walk for days within a maze of bases, stems and guides, of journals, chords and axes—and a thousand more besides. I eat full loads and wings and ribs, a spade grip on my knife, feed mechanism (mouth and arm) is ready for the strife and yet it is but little joy, for everything I lift brings back to mind the dope or drag, the decalage or drift.

In vain I try to stagger through; I side slip and I skid, and if I stall, a sweep-back comes, and down will go the lid. Oh, landing gear and magazine; oh, butt and stock and rod, you'll drive me to a dippy house or under-neath the sod. A violent death at Teuton hands would cause me no alarm—'twould mean a rest from yaw and throw and web and rocker arm.

Now, I am not an aeronaut, perhaps I'll never be one, but when by heart I've learned each part, I never want to see one. I joined to fight the Kaiser and go hunting for the Hun, but 'fore I learn each "technic" terms, the fighting will be done.

L'Envoi

Those blooming terms, I meet with them,
I sleep with them and eat with them;
I drink with them and think with them,
My eyes in sorrow blink with them.
I walk with them and talk with them,
My head just seems to rock with them.
They're here and there and everywhere
To cause me consternation—
And yet one never shows its face
When I am gazing into space
During examination.



On the word One grasp the delicate streamline back of the machine and with the left leg placed firmly on the Trailing Edge —
— swing (on the word two) the right leg round clock wise facing the engine, making sure of clearing the empennage generally
Seesy
Meredith Were in!
R Riley 17
The right leg now being firmly imbedded into the interior, on the word "Three" bring the left leg up smartly and place same carefully within —
always remembering that most machines are fitted with instrument boards control gear seats etc: IMPORTANT - Be careful never to use the foot-holes provided for mounting

TRAINING.—A ribald sketch indicating the degree of intelligence shown by some pupils in the early stages of their careers

The Blood-Stained Spanner or the Missing Mechanic

By A. G. S. Axol

[Editorial Note.—With this week's issue of Aerial Age *we start and finish a grand new thrilling serial by that young and brilliant author of "Flight," whose sundry articles have been appearing in fortnightly parts for some time past.—*Ed.]

SAVE for the howling of the gale that raged without, and the regular beat of Captain (R.F.C.) Gaston Camouflage's heavy tread as he paced up and down the parky flooring of Lady Ima Chauviere's magnificent reception hall, and the irritatingly incessant tick-tock, tick-tock of Ima's Grandfather's clock, not a sound broke the deathly stillness of the night. It had just struck eleven. Would she fail him at the eleventh hour? Surely he had not done wrong in trusting her with the details of his secret mission, upon which so much depended? She would not, could not—Heavens!!—tell Count Kamerad! But no, he dismissed the thought almost before it crossed his mind, as a silvery laugh—hers—caused a deep flush to mount his handsome features at 3,000 ft. per minute. Again that laugh, somewhat high in pitch, and then she burst into the room.

"Ima."

"Gassy."

For a moment he stood transfixed, gazing into her liquid French walnut eyes. Her design was indeed superb. She was some 5 ft. ins. overall length, faultlessly streamlined, and her features were exquisitely carved, especially the entering edge of her chin. Her deeply cambered eyebrows and the negative washout to the corners of her mouth gave a dernière touche to her bewitching features. Her fuselage was covered with the finest quality fabric, supported thereon by expensively-jewelled bracing, and dyed with one of Messrs. Curate's world-famous art colours—a very fast cabbage pink. She had a stately and well-sprung under-carriage, that, as she taxied across the hall, produced a peculiar but none-the-less fascinating oscillation laterally. In her hair, which lay in disturbing eddies upon her head, she wore the famous Gotha diamonds set in a solid gold cabane—a wedding gift from Baron Emile Lyte de Titanine. Such were the goods that dumped themselves before his picture-orbits. (Oh, Henery! Ed.) Unable to restrain himself he threw himself at her feet.

"My love, at last," cried Gaston. "Quick, have you sealed the box I entrusted to your care? You must give it to me at once. In the courtyard below I have a special speedy scout in readiness, the Royal Aircraft Factory's latest combination of all the World's aircraft. Ah! my dear, you have no idea what a wonderful 'bus it is, nothing can touch it—even my trustworthy mechanic, A. M. Doaper, is not allowed to. It has a variable speed-range, and the weight has been cut down to a minimum, thus considerably reducing the centre of gravity. It is provided with an automatic wind-tunnel, which assures that the altimeter and air-speed indicator always show a constant reading, so that they are thus unnecessary impedimenta and are therefore eliminated from the machine's equipment.

"When taxying on the ground," shrieked Gaston, his eyes shining like Verey lights with enthusiasm, "the wheels are connected by bevel gearing to the engine, so that they keep the latter going, a six-and-a-half bladed fan, driven by the slip stream from the wood-screw in front, function to the same end when the machine is in the air."

"Oh, Gaston," cried Ima in an awful whisper, "how wonderful! And does it really fly?"

But Gaston did not reply. He was thinking of his mother's cottage with the roses round the door.

"Yes," he mused, 50 per cent aloud, 5 per cent to her, and 45 per cent to himself, "everything is in favor of a successful journey—— But come," he said, suddenly reviving up, "I have not a moment to lose, but must leave for the front by the back way immediately. I have tarried too long already, for this is Monday, to-morrow will be Tuesday, the next day Wednesday—half the week gone, and still I have not delivered that precious box to the Mess at the Air Board. How can they do without it? Ah! my love, to think that only you and I know the contents of that box—half a pound of sugar!"

(To be continued—perhaps)

(*Continued from page* 150)

of the goggle, but it will be remembered that his report of November 30th refers to the Army Regulation goggle, designed by and made under instructions of Signal Corps, Equipment Division, for which Strauss & Buegeleisen are not in the least responsible although they made the goggle. As soon after the Government Signal Corps order allowed them to do so, they designed and perfected a new shape goggle which overcomes all of the mechanical objections, always apparent in the original Army Standard type. This new goggle has had a marvelous sale and is in almost universal use today.

"How little it interferes with vision is testified to not only by the Bureau of Standard's report now issued, but as well by the continued and satisfactory experience of thousands of aviators.

"That it is nonshatterable and therefore provides safety is evidenced by the fact that literally hundreds of eyes have been saved by its use. In every camp, there are many instances where the use of Resistal has been a real factor for safety.

"It is curious to note that in Day's report a comparison is made of the price charged to the Government on the old style goggle and the price charged to the aviator for the new style. For all the faults that are attributed to the old style goggle, distortion of vision, etc., is due to the fact that the Signal Corps would not pay more than to enable the manufacturer to produce a better goggle, optically speaking.

"It naturally follows, therefore, that the best goggle was furnished by the price the Signal Corps paid, but with the aviator appreciating more the necessity for proper protection, he has been willing to pay and has been anxious to pay a better price to get the proper article than the Government supplied and that is the reason the new style had a little higher price, against which none of the complaints or arguments can be brought.

"It is unfortunate that the large amount of work the Signal Corps had to do in its various departments should have prevented up to now, proper investigation of this matter. That any action in March should be based on a report of November and without knowledge or information as to what has happened since November, in the development of goggles, is indeed unfortunate. The aviator, however, and the commanders of the fields have been closer in touch with the situation. They know the more recent developments and by reason of the simplicity of the organizations at the field they are in a better position to handle this entire subject and will undoubtedly do so.

"Copies of the complete Bureau of Standard's report may be had of Strauss & Buegeleisen who have prepared duplicates for distribution."

Personal Paragraphs

Among the ninety-eight men who received diplomas from the army aviation school at Ohio State University here recently were Russell G. Colt, husband of Ethel Barrymore, the actress, and Philip D. Armour, 3d.

The latter is a nephew of J. Ogden Armour.

Lieut. Joseph Stehlin, winner of the French War Cross and two citations for bravery, and one of the aerial "aces" of the famous Lafayette Escadrille, was injured slightly when he lost control of an aeroplane in which he was flying over the Sheepshead Bay Speedway last week, and was thrown out of the plane, when it was wrecked by digging its nose into the speedway turf. Lieut. Stehlin is only 20 years old and one of the youngest of the French airmen.

Mrs. John T. Woodruff of New York City announces the engagement of her daughter, Miss Anna Louise Woodruff, to Lieut. William Parker Taylor, son of Mr. and Mrs. William O. Taylor of Plainfield, N. J.

Lieut. Taylor is attached to the 183rd Aero Squadron and is now stationed at Garden City. He expects to start for France in a few days.

Two army aviators from Mineola flew over New York in the interest of the War Saving Stamp campaign. During their flight over the city they dropped papers urging the public to buy War Saving Stamps, and also calling for recruits for the Twenty-seventh Division, which is at Spartanburg, S. C. Lieut. Roy E. Ludick and pilot, Henry S. Smith landed on the Sheep Meadow in Central Park. Then while the crowd hurred to the centre of the field to examine the machines, four women members of the National War Savings Stamp Committee sold $3,000 in War Savings and Thrift Stamps. The sellers were the Misses Una Maher, Anna Finerty, Rita Mooney, Mabel Sievers and Mrs. P. O. Altman.

Activities At Long Island School

The Horace Keane School of Flight, at Central Park, Long Island, is becoming the center of attraction for numerous interested spectators in the vicinity of New York. The field is easily reached by automobile and, on week ends especially, it is common to see thirty or more cars lined along the roadway while the occupants cluster around the machines between flights.

The school has a number of pupils who are making flights daily, most of them making rapid progress in the art of flying under the training of Dean I. Lamb, Flying Instructor of the Horace Keane School. Mr. Lamb reported one pupil who has been aloft only ninty minutes and is ready to make landings alone. The pupils are enthusiastic about their work and the manner in which the school is conducted tends to promote rapid progress in handling a military aeroplane.

On Sunday, March 24th, among the passengers carried at the School were Craighton Hale of moving-picture fame, who is a member of the Aero Club, and George F. McLaughlin of AERIAL AGE, who, with some preliminary instructions from Mr. Lamb, took the controls when an altitude of 4,000 feet was reached, circling above the field for about twenty minutes.

S. B. Riley Returns to England

Mr. S. B. Riley, general manager of the extensive Manchester (England) plants of A. V. Roe & Co., Ltd., designers and builders of the Standard Avro training biplanes—recently demonstrated by Lieut. Colonel Charles F. Lee, R. F. C., with startling effect over Washington—and the various Avro types of battleplanes, has returned to resume his arduous war duties after a month's sojourn in the United States.

During his stay Mr. Riley visited the principal aircraft instruction concerns here, and to a representative of AERIAL AGE he spoke most appreciatively of the courtesies extended him by various Washington aeronautic officials and the management of the plants he visited.

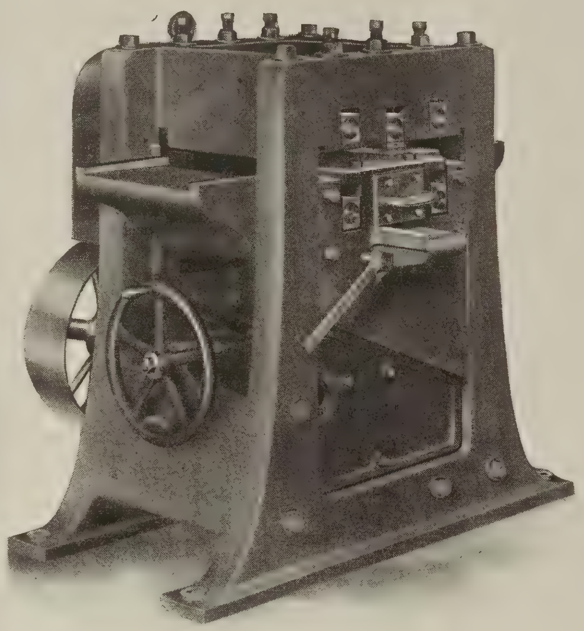
Though but a young man in years Mr. Riley has evidently achieved an enviable reputation as a capacity producer of the "Standard Avro," which has been exclusively adopted by the British Air Board. In the production of this machine there are now seventeen of the principal British aircraft manufacturing firms—in addition to Messrs. Roe's own extensive plants—engaged in meeting the Government's demand for enormous quantities.

Aeroplane Propeller Stock

Toothed at the rate of 100 feet per minute by running it through a

WHITNEY

Toothing Machine



Whitney Scraping and Toothing Machine

If you want to prepare your Propeller stock before gluing up by the quickest—easiest—safest and cheapest method, just put it through a Whitney Toothing Machine.

Many of the Aeroplane Manufacturers, as well as Propeller Makers, are using this machine.

It will pay you to investigate.

J-M Branch in Tacoma

Tacoma has "arrived" as a world port—and Johns-Manville Service, the Service that "covers the continent," is there.

Tacoma's port business has increased 300 per cent over 1913—the highest pre-war total—with a higher figure expected because of its natural shipping facilities, its connection with the Far East trade and the C. M. & St. P. railroad's agreement with the Japanese lines. To these commercial advantages have been added six huge shipbuilding plants, turning out both wooden and steel ships.

For the better service of the shipbuilding and allied interests, as well as the constantly increasing number of manufacturing plants, the H. W. Johns-Manville Company have opened a new branch office at 1015 A Street, Tacoma. Here is carried a complete stock of asbestos packings, moulded and in sheet form, and other well-known Johns-Manville Power Plant Specialties. The advantage of a complete stock at hand lies not only in the aid it affords to a proper selection, but in the prompt deliveries which can be made—a point of service greatly appreciated by packing users.

Tacoma industries thus are assured the same service that every other large city enjoys—another example of the Johns-Manville Service which "covers the continent."

American Fliers Win Praise From French

An appreciation of American aviators in France was received by the press in an official French dispatch, quoting the "Petit Parisien" as follows:

"Our American allies, who are beginning to reinforce our numbers, are already proving their value. They are sportsmen and show much interest in athletic exercises in the training of pilots.

"Among them let us cite the holder of a world's record for running, Ted Meredith, who is finishing his instruction somewhere in France. The famous football and hockey player, Hobey Baker, is already on the front and has two victories to his credit. Sergeant Putnam has been longer at work. He achieved his first success the fifteenth of January, the second the twenty-seventh of January, and his third the fifteenth of March.

"We can have confidence in the aid brought by the American pilots. Before long 2,000 of them, perfectly trained, will take their place in the ranks of our Allied army."

Garabed Giragossian to Pick Five Experts to Test His Invention

Secretary of the Interior Lane is waiting for Garabed T. K. Giragossian to name a committee of five scientists to witness the tests of and to report on the "Garabed," the free energy invention of Giragossion.

Much is claimed for this invention, and an Act of Congress was passed for its secret test. It was provided that a committee of five scientists was to be selected for the purpose to be acceptable to the Secretary and the inventor.

Giragossian submitted more than twenty names to the Secretary. Of this number the Secretary promptly selected ten. From this number five are to be selected by Giragossion.

The names of none of the men will be made public, however, until the tests are completed.

It is claimed by the inventor that this device will take free energy from the air and convert it into unlimited power for all purposes.

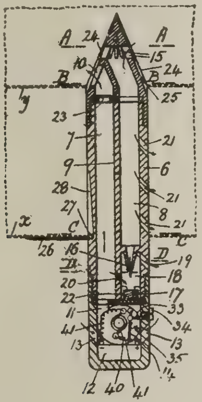
RECENT AERO PATENTS

BY WILLIAM N. MOORE

Curtiss Granted Flying Boat Patent

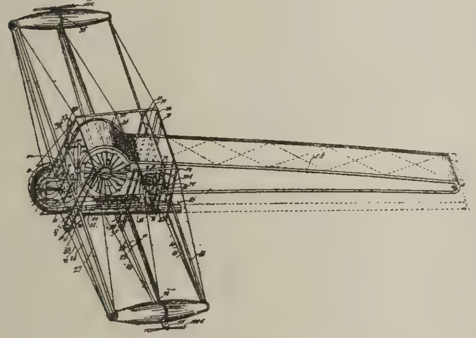
The United States Patent Office granted on February 19, 1918, the claims made in an application filed on December 11, 1914, by Glenn H. Curtiss, the well-known aeroplane constructor of Hammondsport, on behalf of a patent covering the construction of stepped and V-bottomed flying boat hulls. We shall reprint the claim in full next week.

1,139,354. PROJECTILE FOR DESTROYING AIRSHIPS, BALLOONS, AND OTHER AEROSTATS. Reginald Arthur Featherstone-Smith and Meherjibhoy Bomanji Cooper, London England. Filed Sept. 19, 1914. Serial No. 862,501. (Cl. 102—26.)



1. A projectile for destroying airships and the like comprising a shell having an air passage extending therethrough toward the nose end and a gas passage extending therethrough toward the tail end, a gas igniter in communication with the gas passage, openable stops at the exterior of the shell, and an air blower in communication with the air passage.

1,151,419. SPEED-CONTROLLER FOR AEROPLANES. Alexander Blair Thaw, Pittsburgh, Pa. Filed Jan. 29, 1914. Serial No. 815,207. (Cl. 244—29.)



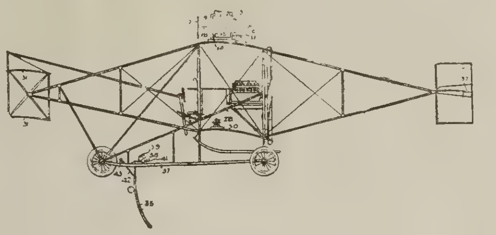
1. A controller is characterized, comprising a yielding air-pressed plane; operating mechanism for the balancing members of an aeroplane; a plurality of electro-mechanical devices for selectively actuating said operating mechanism; a plurality of electric circuits, each embodying one of said devices; a plurality of electric switch members controlling said circuits, one of said switch members being connected with said yielding plane; and a controlling switch for said electro-mechanical devices embodying a movable contact member disposed to be engaged by the ground when landing said aeroplane.

2. A controller as characterized, comprising a yielding air-pressed plane; operating mechanism for the balancing members of an aeroplane; a plurality of electro-mechanical devices for selectively actuating said operating mechanism; a plurality of electric circuits, each embodying one of said devices; a plurality of electric switch members controlling said circuits, one of said switch members being connected with said yielding plane; a controlling switch for all the circuits of said electro-mechanical devices; and an antenna operatively disposed in advance of an aeroplane to engage a supporting medium preliminary to making a landing thereon.

3. A controller as characterized, comprising a yielding air-pressed plane; operating mechanism for the balancing members of an aeroplane; a plurality of electro-mechanical devices for selectively actuating said operating mechanism; a plurality of electric circuits, each embodying one of said devices; a plurality of electric switch members controlling said circuits, one of said switch members being connected with said yielding plane; a controlling switch for all the circuits of said electro-mechanical devices, an antenna operatively disposed in advance of an aeroplane to engage a supporting medium preliminary to making a landing thereon; and means for holding said antenna in out of service position after being moved by contact with said supporting medium.

4. A controller as characterized, comprising a diving plane; automatic means for operating said diving plane; and means for discontinuing the operation of said automatic means, said last-mentioned means embodying a member for engaging the ground when the body of the aeroplane is approaching the same.

1,141,431. FLYING MACHINE. Frank Steinmann, St. Louis, Mo. Filed July 1, 1912. Serial No. 707,124. (Cl. 244—14.)

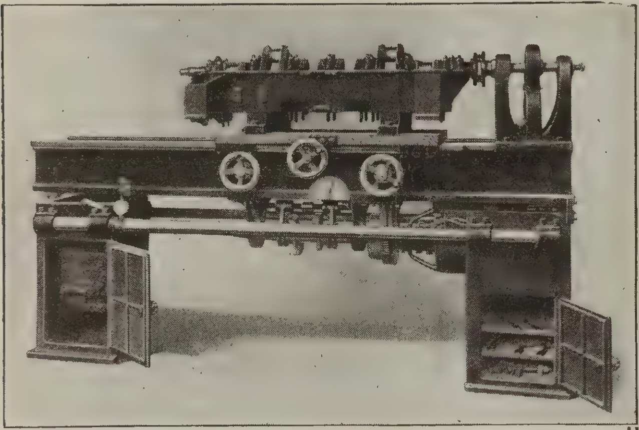


1. In a flying machine, in combination with main sustaining planes, a compressed air actuated tiltable stabilizing propeller located at the extreme outer end of each sustaining plane, and operatively connected to a plurality of air tanks extending longitudinally of the machine and forming, in conjunction with the sustaining planes a base for the machine and also a means for keeping it afloat when alighting on water, means for propelling the machine along a launching rail consisting of a frame attached to the lower part of the base and provided with bearings in which are journaled a drive wheel and a rear landing wheel respectively, a roller grip safety attachment on said frame for guiding the machine along the launching rail and adapted to be disengaged therefrom when an ascending flight is to be made, and lateral cables to balance the machine when it is not in motion.

2. In a flying machine, in combination with sustaining planes, a compressed air actuated tiltable stabilizing propeller located on the end of each sustaining plane, means under the control of the operator for driving the same and setting the same at different angles, a plurality of compressed air tanks running longitudinally of the machine and forming, in conjunction with the sustaining planes, a base for the machine and also a means for keeping it afloat when alighting on water, a frame provided with bearings attached to the underside of the base, a driving wheel journaled in said bearings and adapted to engage with the launching rail, a chain and sprocket drive for rotating the driving wheel, lateral balancing wheels, and a roller safety grip for guiding the machine along the rail and capable of being disengaged therefrom when an ascending flight is to be made.

3. In a flying machine, in combination with sustaining planes a compressed air actuated tiltable stabilizing propeller mounted on the end of each sustaining plane, a pivoted stabilizing plane in the form of a casing consisting of a canvas covered truss frame of slotted pipes extending longitudinally of the machine, means for setting the stabilizing plane to any angle at the will of the operator, comprising a hand wheel, air tanks adapted to act as floats, a wheel frame extending longitudinally of the machine, and a drive wheel and a rear wheel mounted thereon and adapted to engage with a rail, driving means for the drive wheel, and a launching roller grip operated by rods and cams under the control of the operator.

4. In a flying machine, in combination with a sustaining plane, an elevation plane mounted on trunnions supported by suitable standards secured to compressed air tanks constituting a floating body to sustain the machine on water, connecting means extending between said trunnions and forming a housing for a power plant comprising an air compressor and suitable motors, said elevation plane comprising a truss frame of endless slotted pipes extending longitudinally of the machine and parallel to the direction of flight, said truss frame being formed with a large circular front end and tapering to a small circular rear end; means for covering said truss frame, consisting of canvas, balls of suitable material sewed into said canvas at suitable intervals along its sides and adapted to be inserted into the slotted pipes, a shaft passing transversely through the circular front end of the truss frame and suitably supported therein, wind wheels mounted on the ends of said shaft, means for elevating said elevation plane and said wind wheels, main propellers mounted on said elevation plane and driven by suitable gearing actuated from the power planes, and suitable means to drive the air compressor from the wind wheel shaft.



This machine accurately locates, measures and indicates on the dial in ounce-inches the correction needed to produce true running balance. Shafts can be balanced in crank cases or separately.

"Never too many"

We shall never have more airplanes at the front than we can use. That is agreed.

Every added 'plane that we can keep in the air brings the end of the war that much sooner.

Since there's a limit to the number we can build and man, each one must be made to count to the utmost.

Minimum fatigue for the pilots—minimum wear and racking for the 'planes—maximum effectiveness in photographing, gun sighting, bomb dropping,—all these are equivalent to adding more 'planes at no cost in men, material or shipping facilities.

Crankshaft vibration has an important bearing on both personal fatigue and life of the machines. It is eliminated in a few minutes' time, with mathematical precision, by the Carwen method of balancing.

Inner Problems of Aircraft Situation Made Public and Steps Proposed for Solution

Hispano-Suiza Engine

The ABILITY to DO

AT a time when the manufacture of airplanes and engines is of such international prominence as at present, it is important to note the expansion of the Wright-Martin Aircraft Corporation under the leadership of men of known ability.

For the manufacture of the famous Hispano-Suiza engine for all types of airplanes, the character of the organization is noteworthy, supported as it is by the origination of the basic aviation patents.

INNER PROBLEMS OF AIRCRAFT SITUATION MADE PUBLIC AND STEPS PROPOSED FOR SOLUTION

Aero Club of America Protests Against Halting Aviation Section Enlistments

IN a letter sent to President Wilson, Mr. Alan R. Hawley, the President of the Aero Club of America, brings to the President's attention the fact that the Signal Corps is refusing further enlistments for the Air Service, although only one-sixth of the necessary aviators are under training. Mr. Hawley also gives the main inside causes of the present delay in the Aircraft Program, and points out that we are making today another mistake even more serious than the mistake of six months ago, which led to the present delay in aircraft production. Mr. Hawley also points to the steps that should be taken immediately to correct the past mistakes and insure against a costly failure to supply the air forces needed by the Allies to win the war.

Mr. Hawley's letter to President Wilson follows:

"My dear Mr. President:

"A number of men who had applied for admission in the Air Service of the Army have advised the Aero Club of America that they have been notified by the Signal Corps authorities that no further enlistments are being accepted at this time.

"As Secretary Baker's report, published recently, stated there were less than four thousand aviators under training, and knowing that it will take twenty thousand aviators to keep five thousand aviators on the fighting front continuously for one year; and realizing that to lack the trained aviators to supply the necessary replacements would mean defeat for the cause of the Allies, we were amazed to find this condition.

"In answer to our inquiries, we were advised that the reason no further enlistments are accepted for the Air Service is that there is a lack of training fields and of aeronautic equipment and that these cannot be provided because there are no funds available for the extension of the Air Service.

"This is only one of the evidences that the aircraft program is slowing down because of lack of funds. We have been advised by factories that have completed their orders that they also do not have orders to look forward to and to prepare for.

"We submit, Mr. President, that this is a mournful condition which threatens the cause of the Allies more seriously than anything else. Supremacy in the air is to be the key to victory. To achieve and maintain supremacy in the air, the Allies must have the support of the United States. The Allies must be able to count on not less than twenty-five thousand American aviators, so as to insure keeping five thousand at the front continuously for the various duties of the Air Service and for the bombing expeditions.

"The percentage of replacements needed in the Air Service has increased greatly in the past six months and will further increase in the coming year, because there is much more aerial fighting, attacking troops from the air, bombing at low altitudes and night raiding. Aerial fighting is becoming more and more intense; and the anti-aircraft guns are firing more and more accurately and hitting aeroplanes at altitudes of sixteen thousand feet. This increases the casualties among aviators enormously.

"This condition today is analogous to the condition which existed last October in the American aircraft situation as a whole. A large number of training camps had been established, at a cost of $390,000,000, orders for aeroplanes and motors had been placed, and the funds had practically been exhausted. Thereupon the work of developing additional sources of supplies for aircraft and motors practically stopped, notwithstanding the fact that the Italian reverses and the Russian collapse demanded imperatively that our program be tripled in size.

"The Aero Club of America officials urged and pleaded for prompt consideration of this new condition at the time, and pointed out that it was absolutely necessary to immediately give two billion dollars additional appropriations for extending the aircraft program. That was six months ago, when prompt action would have prevented the confusion and mistakes which were subsequently made, partly owing to lack of sufficient appropriations.

"The main cause of the present deplorable condition of our aircraft program was that the authorities in charge tried to make twenty thousand aeroplanes do the work of eighty thousand. The original program did not take into consideration that it takes an average of two aeroplanes to give an aviator the one hundred hours of preliminary and advanced training needed to make him fit for the present-day highly specialized work of a military aviator. Nor did it take into consideration that it takes close to one hundred per cent. replacements per month in aeroplanes and motors to keep aviators equipped for fighting. Nor did it take into consideration that it takes forty per cent, replacements in aviators per month to keep up the fighting personnel of aero squadrons.

"In making this program the fact was overloked that if the plan was to keep five thousand American aviators at the front, it was necessary to train twenty-five thousand. Therefore, there would be required fifty thousand preliminary and advanced training aeroplanes with which to train them speedily. The number of aeroplanes under construction today is not sufficient to even give the preliminary and advanced training to the number of aviators the United States must supply within the coming twelve months.

"There was also overlooked the fact that to keep five thou-

AERIAL AGE WEEKLY HAS BEEN ADMITTED TO FULL MEMBERSHIP IN THE AUDIT BUREAU OF CIRCULATIONS—COPIES OF REPORT WILL BE MAILED TO ADVERTISERS ON REQUEST

sand aviators equipped for action, there would be required an average of two thousand aeroplanes of different types per month, or a total of twenty-four thousand machines of different types during the twelve months.

"Having overlooked these very important considerations, the authorities could not undertake to supply all the aeroplanes needed out of the twenty-two thousand planned. The Italian and Russian reverses created imperative needs, and the authorities received cables requesting thousands of aeroplanes of different types. Lacking the funds necessary to place additional orders, the authorities changed the orders which they placed, so as to meet the requests from France. As the requests from France and the suggestions from the different Allies were for different types of machines, the authorities kept on changing the orders, so as to supply those machines for which there seemed to be the most pressing need. This led to the continuous changes which caused the setbacks which have resulted in the aircraft program—which is still the same program made at the time when Italy was victorious and Russia was still fighting—being behind by several months.

"Had the authorities been in a position to place additional orders whenever they received cables asking for a given number of machines of a given type, instead of having to change orders for machines under construction, today the original program would be nearly delivered and an additional program would be well under way.

"Today we are making the same mistake that was made then. We are stopping the enlisting of aviators and no steps have been taken to extend the program to meet the new conditions which have arisen, and which, unless they are met promptly, may result in Allied reverses and public condemnation of your Administration, not only from the American public, but also from the Allies.

"It is tragic to us, Mr. President, to know that while aeroplanes and aviators are needed so badly to fight this fight for civilization and humanity, hundreds of manufacturers who could be making aeroplanes and motor parts are kept in forced idleness for lacking of orders, and thousands of patriotic young men who are anxious to join the Air Service and go to France and do their share towards winning the war, are told that no further men are being taken in the Air Service.

"The delay in producing the Liberty motor cannot be held responsible for not giving preliminary and advanced training to aviators. This training, which includes cross-country flying, bomb-dropping, shooting at moving targets from aeroplanes, could be given with existing types of machines and motors.

"We submit, Mr. President, that action must be taken promptly.

"We agree with the members of Congress who advise us that those in charge of the present aircraft program have failed to make good and that it is hardly possible to expect better from the same organization if conducted by the same authorities on the present plan of action.

"We have followed the aircraft program step by step and are familiar with the inside problems that have caused the delays. These causes are numerous, but the main ones are:

"(1) Lack of concentrated responsibility, authority and control in the management of aerial matters.

"(2) Lack of sufficient appropriations to extend the aircraft program to meet the military needs of the Allies.

"(3) Lack of touch between the authorities dealing with the strategic side of the war and the authorities having charge of the supplying of aircraft and aviators needed to build American and Allied air forces.

"(4) The lack of a Government department having the authority and organization necessary to deal with all aircraft matters and prevent delays due to division of responsibility, bureaucratic jealousies and official squabbles over matters of departmental jurisdiction, duplication of efforts, etc. The present Aircraft Board is only an advisory board and has no power to act or to get the necessary organization to extend or carry out an extended aircraft program.

"To correct the situation, two successive steps must be taken, as follows:

"(1) The immediate appointment of an Assistant Secretary of War and an Assistant Secretary of the Navy to represent the Army and Navy, respectively, in the Aircraft Board. This is to solve the immediate problems while the second step is being taken.

"(2) The creation of a Department of Aeronautics, based on the British plan, which places the Air Services under a separate Department of Aeronautics, the head of which is independent of, although cooperating closely with, the War and Navy Departments.

"The British Government went through every one of the troubles we have gone through in connection with our air service. The official reports of the investigation of the British Air Service in 1916 shows that there were scandals and charges, counter-charges and confusion, just as we have in the United States today. After three years of trying different plans, the military and naval authorities and other branches of the British Government came to the conclusion that the only solution was a separate Department of Aeronautics, with an Air Minister at the head, whose functions are identical with the duties of the War Minister and the First Lord of the Admiralty.

"A separate Department of Aeronautics is the only solution to all the problems of building the air forces needed to win the war.

"We must add that many of the officials in charge of the aircraft program and the members of their staffs are able men who, if placed in a Department of Aeronautics and given the power necessary to act and to get together an efficient organization and the necessary funds, will quickly save the situation and enable the United States to do its share in the air this year.

"It is well to add that an important consideration that led to the creation of the Air Ministry in Great Britain was the knowledge that Germany is planning extensive aerial mail, express and passenger transportation lines, to employ the output of her aircraft factories after the war. Germany's plans are extensive enough to employ tens of thousands of aircraft. This would give her a reserve air fleet large enough to blow England, France or Italy off the map overnight.

"As was brought out in the House of Commons by Lord Montague, aircraft can be turned from vehicles of transportation to war machines by the simple process of substituting bombs as cargo. Any nation that overlooks this fact may pay dearly for its oversight.

"We all hope, of course, that some agreement may be reached between the nations which will guarantee against such a horror as the bombing of a nation out of existence overnight by another nation having tens of thousands of aeroplanes. But the present war has shown that hopes does not save nations from the outrages of aggressors. As a matter of fact, Germany's first air raids of Great Britain were conducted by Zeppelins, which were employed for passenger carrying before the war. So while keeping our hearts in the right place, we must be ready to protect the Republic and the rights of Humanity and the Cause of Civilization. To do this will require direct control and supervision of military and commercial air fleets, and this can only be done by a well organized Department of Aeronautics.'

"In conclusion may we point out that in the past events have always proven that our suggestions, which were termed as excessive by some people at the time they were made, were most conservative. We beg you to judge these recommendations accordingly.

"Assuring you of the hearty cooperation of the Aero Club of America and its affiliated Aero Clubs and cooperating organizations, I beg to remain

Very truly yours,

(Signed) ALAN R. HAWLEY,

President, Aero Club of America.

THE NEWS OF THE WEEK

4,500 Men to Be Drafted for Aviation Service

Provost Marshal General Crowder announced that 4,509 draft registrants will be called to equip themselves to assist in the maintenance of the Air fleet. The call was made on Illinois, Minnesota, Iowa and Indiana, and men will be given a thorough training course in woodworking and gas engine operation and repair at fourteen educational institutions selected by the government throughout the country.

The voluntary induction system will be tried, but where the State fails to produce its quota, local boards will be directed to conscript enough men to fill it. It is specified that the registrant must have had a grammar school education.

. The schools and quotas which each State is directed to send follows:—

Minnesota—Three hundred men to Carnegie School of Technology, 500 to University of Cincinnati, 500 to University of Minnesota, 189 to Pennsylvania College, 320 to University of Pittsburgh.

Illinois—One hundred men to University of Chicago, 200 to Lewis Institute, Chicago; 100 to Northwestern University, Evanston, Ill.; 300 to Bradley Polytechnic Institute, Peoria, Ill.

Iowa—One hundred to New York University, 400 to University of Wisconsin; 500 to Rahe Automobile and Tractor School, Kansas City, Mo.; 500 to Sweeney Auto School, Kansas City, Mo.

Indiana—Five hundred to Purdue University, Lafayette, Ind.

Lawson Aircraft Company Expanding

According to a statement in the Milwaukee Journal, the Lawson Aircraft Company of Green Bay, Wisconsin, is about to erect a $500,000 plant in Milwaukee and will move its organization to the new plant. The reason for removal from Green Bay is that more capital can be raised in Milwaukee. The plans for the refinancing of the Lawson Company on a larger scale are already under way.

Count De Limur, Aviator, Marries Miss Ethel Crocker

Comte Andre Marie Adrian de Limur, a pilot in the French flying corps married Miss Ethel Crocker, daughter of Mrs. William H. Crocker, of New York and Burlingame, Cal. The wedding was hurried, as Comte de Limur, who has been on active duty in France, is here on only a brief leave of absence. Many distinguished and prominent members of New York society attended the wedding.

No More Untrained Aviators to be Sent to France

According to E. Percy Noel, of the New York Globe, from now on practically no pupils or pilots will be sent to France to begin or complete their training. Already one advance school, which was partially borrowed from the French, has been abandoned by the Americans. Elementary and advanced schools developed from a French nucleus or wholly created in France by the Americans will become aviation reserve depots for trained pilots.

These pilots arriving from home and also squadrons of enlisted men will have equipment and opportunity for practice so as to be tuned up to top pitch flying ability until ordered to the front. Pupils from ground schools and also military pilots have been sent to France in the past because of the lack of facility principally in the matter of aeroplanes and instructors for their training at home. Until the latest types of the fastest machines could be reproduced in America it was impossible to give the higher class of instruction which their pilots require.

King George Praises American Airmen

Reuter's correspondent at British headquarters in France, describing King George's trip to the front, says:—

"In the course of an inspection the King visited an aerodrome, where he inspected an American section, the members of which he congratulated upon their fine and smart appearance, praise which was well justified, for a livelier looking set of lads never yet swore to drive the Huns out of the air.

"The King spent a crowded fifty hours in France, moving about freely among troops who had taken part in the first onrush of the German offensive."

Gas Used for Testing Aero Motors

Recently the Detroit City Gas Co., an American Light and Traction Co. subsidiary, sold some $1,250,000 bonds, the proceeds to be used to finance the additional plant extensions due to the increased demand for gas in munition plants. This gas, it is learned, is being substituted for gasoline in testing aeroplane motors. So comprehensive is the aero motor building business that this new use for gas in Detroit has increased the daily demand 5,000,000 cubic feet.

Lieut. Col. Henry B. Joy, now serving in France, resigned as president of the Packard Motor Co. to give all his time to war service.

Special Aid Society Continues Its Effective Work

The Aviation Committee of the National Special Aid Society, Inc., of No. 259 Fifth avenue, which is dedicated to the work of collecting gold and silver, as well as the baser metals in the forms of trinkets, coins, &c., and disposing of them for cash, has been purchasing supplies needed by American aviators, mostly articles not yet provided by the government.

Since September the committee has raised $40,000. It has utilized this sum to purchase leather, fur lined helmets, flying coats, flying breeches, aviator mittens, boots, trench coats, goggles, sweaters, socks, blankets, mattresses and cots.

All the German coins contributed will be melted up and sold, and the receipts turned to good account for the equipment of our fliers.

With Our Boys "Over There"

Lieut. Harold T. Hambleton has brought down two German airmen, according to a letter received by his parents, Mr. and Mrs. William G. Hambleton of New York.

The bringing down of another German aeroplane has been credited to Paul F. Baer, of Fort Wayne, Ind., a member of the Lafayette Flying Squadron.

He toppled over a two-seated biplane recently. Friends claim that Baer brought down two machines on the same day. Only one of these, however, has been credited to him officially, but the other is under investigation. Baer is officially credited with two machines shot down, the other victory having been achieved last week.

Frank L. Baylies, of New Bedford, Mass., a former member of the American Field Ambulance, shot down a German machine last week.

David Putnam, of Brookline, Mass., a member of the Lafayette Escadrille, has brought down two more German aeroplanes, making a total of five, of which four are "official." He was attacked by three monoplanes. After a sharp fight he brought one down and the others fled. Later Putnam was attacked by two biplanes and brought down one of them.

Putnam was decorated with the French War Cross and promoted to be Sergeant. He has not yet obtained his transfer to the American air forces.

At the Aviation Training Fields

The first Liberty motor has arrived at the University of Illinois ground school, where it will be used for instruction purposes.

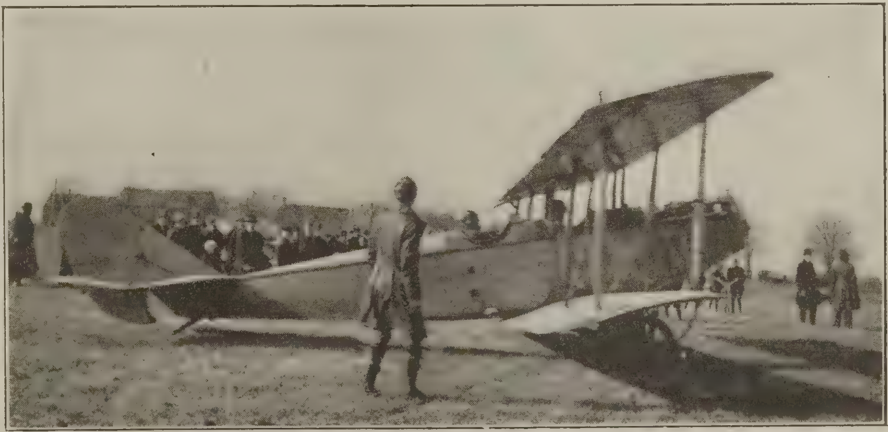
The Flying Cadets at Love Field, Texas, are now receiving instruction in cross-country flying. Landing fields have been provided for at several towns nearby.

The Navy Department made its first balloon observations of New York harbor recently, and sent several captive balloons from the decks of vessels to different altitudes. The tests began at 1 o'clock and ended at 5 o'clock.

The aeronaut who was the first to ascend suffered a mishap. When the balloon was a considerable distance up, the cable slacked and the balloon floundered in the water. The aeronaut got from under the bag and was bauled aboard his ship. The balloon was pulled in by cable.

Several other balloons went up successfully. Each balloonist carried a telescope and was connected by telegraph with the vessels. The balloonists made the observations and telegraphed the results to the ships' decks.

A half dozen big machines hovering over a Texas town no longer attract attention. Texans have come to regard the army fliers, with their dives, loops, nose spins and similar feats, as very ordinary. The frequent cross-country flights between Fort Worth, Dallas, Wichita Falls, Waco, Houston and San Antonio no longer send the barnyard flocks hurrying to cover. Even the chickens have come to look upon the aviators and their big machines as everyday visitors.



A Curtiss JN training tractor at the Horace Keane School of Flight, Central Park, L. I.

Army Appoints Board to Select Locations for Aerial Coast Patrol Sites on the Pacific

A Board has been created by the War Department for the purpose of locating aero coast defense squadron sites and balloon coast defense company sites in the South Pacific Coast Defense District, which centers at San Francisco, and for the North Pacific Coast Defense District, with headquarters at Seattle, Wash.

The members of the Board are as follows: Major Edwin B. Lyon, A. S., S. C.; Capt. Frank Stockdale, Medical Reserve Corps; First Lieut. Clarence G. Spencer, A. S., S. R. C., and Mr. C. B. Feber, A. M. E. A fifth member is to be an officer designated by the Coast Defense commander.

Aero Mail Landing Place for Philadelphia Selected

Arrangements have been made for the lease of a site for the postal service aeroplane landing field at Philadelphia, the Post Office Department announced. The land is in North Philadelphia, just outside of Bustleton on the Lincoln Highway and about twenty-five minutes from the Philadelphia post office.

Work of constructing hangars will begin at once. The field will be ready before May 15, when the aeroplane postal service between New York, Philadelphia and Washington will be in operation.

Emplacements for Anti-Aircraft Guns to be Erected in New York

Action has been taken by the War Department toward protecting New York and vicinity from possible air raids. It was learned that the War Department has awarded a contract to the White Fireproof Construction Company for the construction of two concrete anti-aircraft gun emplacements in Mount Morris Park, Fifth Avenue and 120th Street; Tompkins Square Park, Avenue A and Seventh Street; Fort Greene Park, Myrtle Avenue, Brooklyn; Lincoln Terrace Park, Greenwood Cemetery, and Mount Olivet Cemetery, Brooklyn.

The plans of the War Department call for the construction of two concrete anti-aircraft gun emplacements on each site. The work on several of these began some time ago. The bases will be large blocks about eight or ten feet square and ten feet deep. It is believed that additional emplacements will be built soon after those planned have been finished.

The work is proceeding under the general direction of General Theodore Bingham, who is in charge of the defensive works of the eastern and southern entrances of New York Harbor.

It could not be learned when the anti-aircraft guns for the emplacements would be available for the city's defenses.

No More Civilian Instructors

The War Department has made a new ruling that civilian instructors will no longer be used in aviation schools and only commanding officers will do the instructing.

Six Aeroplanes for Camp Dix

According to information received by the New York Sun from Camp Dix, six military airships will arrive during the course of the week, permitting troop movements under conditions approximately war conditions on the front.

The planes will be assigned with their operators to the Signal Corps. Immediately upon their arrival, it was stated that the division and regimental commanders will work out field problems. Their solution will require the functioning not only of the aviators, but of the observers, photographers and wireless operators in the duties which they are to perform at the front. Lack of these aero units has made it impossible to secure approximate war conditions in the practice manoeuvres. The photographs and observations obtained by the flyers will make it possible for the men of the 303rd Engineer Regiment to learn exactly how efficiently their work of concealment has been carried out.

Steel Aeroplane Traps for Allied Aviators Report from Holland

At Zeebrugge, the German naval and aerial base on the Belgian coast, the Germans have adopted a new method of catching hostile airmen, according to an Associated Press report.

Toward evening, the "Telegraaf" (Amsterdam) frontier correspondent reports the Germans send up twenty captive baloons, without crews and attached to electrified steel cables. The electric barrier is said to constitute a menace to all airmen coming in contact with it.

The Germans, it is added, have also manufactured a new and improved type of aeroplane. It is fitted with three propellers, one being so arranged it can keep the aeroplane stationary above a certain point for a few minutes, thus permitting the bomb thrower to aim with greater accuracy.

Oregon Aids Aircraft Production

Oregon, which has been supplying a good proportion of the spruce used in the construction of aircraft, is now making efforts to enter into other fields of the aircraft production program, according to an editorial in "The Oregonian," of Portland. Colonel Disque, who is in charge of the Spruce Production Division of the Signal Corps, with headquarters in the Yeon Building, Portland, has recently let to Oregon planing mills contracts for the manufacture of aeroplane stock into wing beams.

The editorial then urges manufacturers to go into the production of linen which is essentially needed for the aircraft programme. The flax raised in Williamette Valley is equal to the best raised in Ireland.

Japanese to Prepare for German Air Raids

The Japanese army has formulated a definite plan to build 1,000 aeroplanes in the fiscal year, 1918-'19, and has sought the consent of the Imperial Diet, according to the "Osaka Asaki."

The immediate cause of the move was the possibility of Germany succeeding in establishing aircraft bases in Siberia along the Pacific seaboard.

"Let us suppose," Major Onokichi Isobe is reported to have said in an interview, "that Germany is able to establish a base at a point as near to our country as Harbin, for example. The enemy craft could make Japan in about seven or eight hours. Germany had about 1,000 aircraft on the Russian front. Suppose the Teutons were to decide to threaten the Far East through Russia. All that is necessary for our people to do is to recall what Germany has done to London and Paris through the air route."

Major Isobe and Major Sawayanagi are about to organize a company for the manufacture of aircraft in Japan. The company is to start with a capital of 500,000 yen and it intends to import motors from the United States.

Military Aeronautics in South and Central America

Arturo Escario, a Paraguayan aviator, has been sent to Europe to acquire the most modern aeroplanes for use at the Army Aviation Training School near Asuncion, Paraguay.

According to "A Noite," a daily newspaper of Rio de Janeiro, military aviation schools are to be established at Sao Paulo, Parana and Rio Grande do Sul, Brazil. Acero Marquez, a Brazilian aviator, will have charge of the school at Sao Paulo.

The Cuban Army has organized an Aviation Corps. Twenty aeroplanes have been ordered from the United States. Santiago Campuzano, who has seen active service on the front in France, is in charge of the instruction.

Waco Aviators Give New York "Giants" Hard Battle

In an exhibition game at their southern training camp, the New York "Giants" found worthy opponents in the "Waco Aviators," who held the National Leaguers to a 3 to 0 score.

About thirty aeroplanes soared over the ball field, doing stunts for the boys, including the famous nose spin and the Immerman dive. One daring fellow, at a height of 3,000 feet, turned eight successive loop-the-loops, while others dropped from high altitudes almost into the ball field.

Arkansas "Hayseeds" Fear Airmen's Stunts Will Scare Mules

Contending that aeroplanes flying overhead and landing in the vicinity would scare mules, smash down growing crops and cause negro laborers to leave their work to watch the birdmen, farmers of Arkansas, across the Mississippi River from Memphis, refused to lease land to the government to be used as a landing place for military aviators, training at Park Field. Eight landing places were secured in the immediate vicinity of Memphis.

Seaplane Destroys U-Boat, Despite Three Destroyers

Under a heavy attack from three German submarines and three German destroyers, a British seaplane recently persisted in her efforts againstst another enemy U-boat, and succeeded in sinking it before being damaged by the fire of the other enemy warships, says a recent Associated Press dispatch. The seaplane was on patrol duty at 8:30 o'clock in the morning when a submarine was sighted on the surface with a man standing forward by the gun.

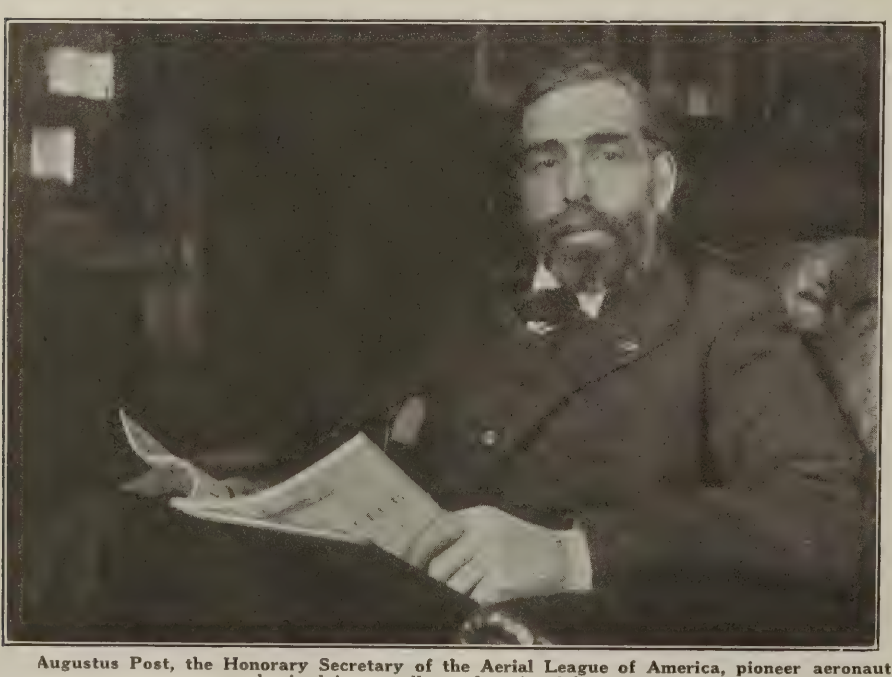
Increasing her speed, the seaplane dropped to an altitude of 600 feet and released a bomb. As she swooped around to repeat the attack, a shell from the U-boat burst in the air fifty feet from the propeller. It was seen that the bomb had made a direct hit, a big rent being visible in the deck of the submarine. Just then out of the mist ahead three more enemy submarines, followed closely by three destroyers appeared.

All six vessels maintained a hot fire against the seaplane. However, a second bomb was dropped on the disabled U-boat. It exploded fifteen feet ahead of the bow of the submarine. The whole craft shook and then sank quickly in a pool of oil, bubbles and wreckage. The seaplane, having no more bombs, and as the destroyers were coming near, returned to its base.

Seaplanes also have accounted for three other submarines. In one case two large seaplanes attacked a submarine on the surface and with two Germans standing on the conning tower. One plane dropped a bomb to the starboard of the U-boat, while the other placed one squarely in front of the conning tower. The explosion of the second bomb was followed by several explosions within the submarine, which disappeared.

Diving from a height of 4,000 feet to 1,200 feet, another seaplane dropped a depth charge on the spot where a submarine had disappeared. When the water subsided, the shape of the submarine could still be seen below the surface and a second bomb was dropped, "after which the ship disappeared."

An enemy submarine with two periscopes and about two hundred feet in length was sighted by a seaplane on patrol duty. The seaplane descended 3,300 feet to a height of 800 feet and dropped two bombs as the Germans submerged. One of the bombs made a direct hit just behind the conning tower. The submarine turned upside down and sank. Oil and wreckage later came to the surface.



Augustus Post, the Honorary Secretary of the Aerial League of America, pioneer aeronaut, who is doing excellent educational lecture work

NAVAL and MILITARY AERONAUTICS

Key to Abbreviations

AAD—Assigned to active duty.
ADO—Report to Aviation Supply Depot, Dayton, Ohio.
AEF—On duty with the American Expeditionary Forces.
AGC—Report to Aviation Supply Depot, Garden City, L. I., N. Y.
AHT—Report to Aerial Gunnery School, Houston, Texas.
AMV—Report to Aviation General Supply Depot, Morrison, Va.
AOV—Report to School for Aerial Observers, Hampton, Va.
APR—Report to School of Aerial Photography, Rochester, N. Y.
BST—Report to Brooks Field, San Antonio, Tex.
CAF—Report to Carlstrom Field, Arcadia, Fla.
CAG—Report to Camp Hancock, Augusta, Ga.
CAP—Commissioned as Captain, Aviation Section, Signal Corps.
CCI—Report to Chanute Field, Champaign, Ill.
CDT—Report to Aviation Concentration Camp, Dallas, Texas.
CGC—Report to Aviation Concentration Camp, Garden City, L. I., N. Y.
CGS—Report to Aviation Concentration Camp, Greenville, S. C.
CLR—Commissioned as Colonel, Aviation Section, Signal Reserve Corps.
CMV—Report to Aviation Concentration Camp, Morrison, Va.
COL—Commissioned as Colonel, Aviation Section, Signal Corps.
CPR—Commissioned as Captain, Aviation Section, Signal Reserve Corps.
CRI—Report to Chanute Field, Rantoul, Ill.
CSO—Report to the Chief Signal Officer, Washington, D. C.
CUI—Report to School of Military Aeronautics, Cornell University, Ithaca, N. Y.
CWT—Report to Call Field, Wichita Falls, Texas
DAF—Report to Door Field, Arcadia, Fla.
DIK—Report to Camp Dick, Dallas, Tex.
DIS—Honorably discharged from service.
EEP—Report to Essington Field, Essington, Pa.
ELA—Report to Eberts Field, Loanoke, Ark.
EOT—Report to Ellington Field, Olcott, Texas.
FLR—Commissioned as First Lieutenant, Aviation Section, Signal Reserve Corps.
FLT—Commissioned as First Lieutenant, Aviation Section, Signal Corps.
FOB—Report to Fort Omaha Balloon School, Omaha, Neb.
FRF—On duty requiring regular and frequent aerial flights.
FSO—Report to Fort Sill School for Aerial Observers, Fort Sill, Okla.
GIT—Report to School of Military Aeronautics, Georgia Institute of Technology, Augusta, Ga.
GLC—Report to Gerstner Field, Lake Charles, La.
HHN—Report to Hazelhurst Field, Mineola, L. I., N. Y.
JHU—Report to School of Military Aeronautics, John Hopkins University, Baltimore, Md.
JMA—Rated as Junior Military Aviator.
KST—Report to Kelly Field, So. San Antonio, Tex. (When specified in the order, the number of the field is given in parantheses)
LDT—Report to Love Field, Dallas, Tex.
LHV—Report to Langley Field, Hampton, Va.
LTC—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Corps.
LTR—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Reserve Corps.
MAJ—Commissioned as Major, Aviation Section, Signal Corps.
MDO—Report to McCook Field, Dayton, Ohio.
MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MMP—Report to Middletown Aviation Supply Warehouse, Middletown, Pa.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PRC—Appointment to Aviation Section declined; prefers retaining previous commission.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
REL—Relieved from present duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRC—Report to Riverside Field, Riverside, Cal.
RRV—Report to Richmond Aviation School, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
TFT—Report to Taliaferro Field, Fort Worth, Texas. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WFO—Report to Wilbur Wright Field, Fairfield, Ohio.

Note 1. Report to Camp John Wise, San Antonio, Tex.

Note 2. Report for temporary duty to points named in order given.

Note 3. Report to New York City for duty with department aeronautical officer.

Note 4. Report to School for Radio Mechanics, Austin, Tex.

Note 5. Report to Signal Corps supply depot, Detroit, Mich.

Note 6. Report to Signal Corps Aviation Mechanics' Training School, St. Paul, Minn.

Note 7. Report to district manager of inspection, New York, N. Y.

Note 8. Report to Hoboken, N. J.

Renovating and re-assembling aeroplanes after a period of service at the front. (British Official Photo.)

INVESTIGATIONS INTO THE AEROPLANE SITUATION

A Chronological Report of Events in Washington

THREE investigations are under way to discover why the aircraft program is 90 days behind its schedule, as claimed by the Senate Military Affairs Committee.

One is being conducted by Howard E. Coffin, chairman of the Aircraft Board, who is determined to run down the various reports and rumors; another by H. Snowden Marshall, chairman of the committee appointed by the President, who is working with the super-war council, and a third is being made by Gutzon Borglum, New York sculptor, who has a mysterious part in the situation.

Mr. Marshall's duties will include the investigation of the whole matter of delayed production. Mr. Coffin is working more specifically to run down reports and rumors of troubles in making the Liberty motors, which are believed in the main to be unfounded.

Mr. Coffin left Washington to make a complete tour of all the plants, and his report will be checked up later with the two others as well as those of officers of the Signal Corps whose duties include supervision of any mechanical or production irregularities which might develop.

March 26th

Senator Harry New, of Indiana, a member of the Senate Military Affairs Committee, told the Senate the War Department had not only failed to send a single aeroplane to General Pershing, but also will be unable to complete more than thirty-seven aeroplanes by July 1 out of last summer's programme calling for 12,000 planes.

Senator Lodge said:

"We know here and we have known for weeks, as the Germans have known, that we have no fighting planes in France. The Secretary of War spoke a short time ago of our beginning to send fighting planes to France. He said the number was small, but we had begun to send them. We returned at that time th etwo French models which we had had here. Since then I believe one American plane has gone; it may be on the water now; it may have been landed.

"The heavy Liberty motor, according to the best information I can get, may be developed so as to furnish adequate power for bombing planes. The light motor does not show a capacity for fighting planes. We have not a fighting plane in France. The front where our men are is not defended in the air. The French and the English have use for every plane they can bring up, and our men are not defended at all.

"We have spent $640,000,000 for aeroplanes in the last year, and we have not a fighting plane in France. I was shown a statement from the Aero Club of America, saying what was needed was money—three thousand million dollars to build aeroplanes. We have granted powers and we have given money without stint; but appropriating money and granting powers will lead to nothing unless the money is wisely expended and the powers are efficiently exercised.

"The facts I have recited in regard to aeroplanes are known to Germany. It is time our people understood them."

Though hampered by military censorship, the Aircraft Board, through a high official, turned on its accusers, according to a despatch in the *N. Y. American.* The charge made in the Senate that not one American built aeroplane is flying at the front is flatly denied. At the request of the Allies themselves it was stated America had rushed men and materials, rather than assembled machines.

Thousands of skilled shopmen from American aircraft and motor factories are in France and England making aeroplanes for our forces abroad. Thousands of tons of aeroplane material have kept pace with them. They are no less American aircraft for having been built abroad, the Aircraft Board claims.

The Liberty Motor is being used in quantity according to a most authoritative source of information, in the Aircraft Board. The period of test with the motor has passed; quantity production is established; the Allies have a high opinion of the U. S. twelves and "are asking for all we can send."

Referring to the Gutzon Borglum charges of incompetency, an official of the board denied that the Liberty Motor failed in a test at Mineola because a crankshaft broke. Another cause, unconnected with the motor, it was said, caused the plane to fall and the crankshaft was bent.

"Substantially, we are not behind time in the matter of the training aeroplanes, of which we have about 2,000," said Senator Hitchcock, in the Senate debate. "When I stated that an investigation was being made, I meant an investigation to develop who is responsible for the present delinquency of combat aeroplanes. We have every assurance in the Military Affairs Committee that a certain number of combat aeroplanes will be ready for delivery July 1. I mean the highest type of combat aeroplanes."

"The Senator does not seem to have the understanding of the term that the Aircraft Production Board has," replied Mr. Poindexter. "If I am correctly informed, we never shall be able, under the administration of this board, to see as the product of American genius the spectacle of a battle plane such as that exhibited to us here on Sunday afternoon, because it is not the intention of this Administration to make those planes."

"The Senator is in error, unles sthe committee is entirely misinformed," rejoined Senator Hitchcock.

"The committee has been misinformed," insisted Senator Poindexter.

"Last summer the Aircraft Production Board, in an excess of sanguine expectation, promised the country an enormous number of combat planes for a certain date of this year," explained Senator Hitchcock. "There were to be 20,000 of them early in 1918. Later this contemplated output was reduced to 17,000, then 15,000 and now it is 2,000 by July 1."

"A gentleman high in the Aircraft Production Board told me that some mysterious, unknown influence was putting a blight on the efforts of the board," replied Senator Poindexter. "He could not explain it. Now there was difficulty in getting spruce, yet there are quantities of it in my State and in Oregon. I, personally, have presented to the board offers of producers to deliver all the spruce the Government wanted, yet no notice was taken of it. The Government did not have the spruce, and it needed it to make the aeroplanes. It could have had it at its own price."

Senator Borah read from Mr. Borglum's report commenting on aircraft production, under date of January 2, in a letter to the President: "The situation indicates a terrible state of confusion and irregularity, as reports show, due to self-interest and intrigue, together with a predetermination of thwart the efforts of the nation."

Senator New of Indiana interjected the remark that the "aeroplane situation had not been exaggerated" by the Senators in the debate.

Senator Johnson of California asked Senator New if the latter, as a member of the Military Affairs Committee, could tell the aircraft program up to July 1 of this year.

"I think, while I had not intended to mention it, it is fair and just to say," replied Mr. New, "that the original program called for delivering in France 12,000 combat planes by the first of next July."

"Then I ask the Senator," urged Mr. Johnson, "if he can answer, if it violates no confidence, how many were delivered, or how many will this Government deliver on the first day of July in France?"

"Thirty-seven," replied Senator New.

"One of the statements made today," Senator Johnson proceeded, "is that it is in testimony before the Military Committee that the condition of our boys in the trenches today is such that, without let or hindrance, German planes are flying over them, and flying so low that our boys are shooting at them with revolvers. I want to know whether that is the testimony before the Military Committee?"

"It is," assented Senator New.

March 27th

The Senate Military Affairs Committee, learned through Colonel E. Lester Jones, head of the aviation supply division, that only one aeroplane had been shipped to Europe, according to the New York *Herald.*

The Committee on Public Information — the Creel Bureau—was called to account for sending out what Senator Wadsworth, of New York, called "misleading propaganda" about the progress of aviation production. The Military Committee voted to demand the suppression of pictures and captions, released to newspapers of March 30, giving glowing accounts of the large number of aeroplanes shipped to France.

In addition to the fact that but one aeroplane has been shipped to France the Senate Military Affairs Committee learned from Colonel Jones that twenty aeroplanes destined to France had been held up at Dayton for further experiments.

Senator Wadsworth called Colonel Jones' attention to the captions mailed by the Committee on Public Information to accompany photographs released to newspapers of March 30. The captions gave exaggerated accounts of the progress of the aircraft programme. They referred to hundreds of aeroplanes shipped to France and thousands more to follow soon.

The committee promptly summoned to the witness stand Laurence Rubel, head of the picture section of the Committee on Public Information. He said that the captions had been written by an assistant, Morris Strunsky. He had questioned Mr. Strunsky, he told the committee, and Mr. Strunsky informed him that he had written the capitions upon the basis of information contained in an official statement of Mr. Baker, Secretary of War.

"He told me Mr. Baker's statement was to the effect that 3,500 planes or parts of planes had been sent to France," said Mr. Rubel.

The committee voted unanimously to demand the suppression of the captions and photographs, and Mr. Rubel said he would comply.

March 28th

Investigation into delay in the aeroplane program was begun by the Senate Military Committee behind closed doors after several days of discussion in the Senate.

Members of the committee were pledged to secrecy, and Chairman Chamberlain announced that no statement would be issued until the inquiry had been completed.

Major General George O. Squier, Chief Signal Officer, and Colonel Deeds were the first witnesses called. They remained with the committee nearly four hours. The committee plans to hear Major General Franklin Bell, who has just returned from a visit to the American front in France. Later Commander Briggs of the British Royal Flying Corps, Colonel Waldon of the American Signal Corps, and Howard Coffin, Chairman of the Aircraft Board, will be called.

March 29th

Inquiry into aeroplane production was continued by the Senate Military Committee behind closed doors, with no indication when the investigation would be completed. Commander Briggs of the British Flying Corps was questioned for several hours, and later Major General Squier of the Signal Corps conferred with Senator Chamberlain of Oregon, Chairman of the committee.

The investigation, according to various Senators who have been present, has not revealed much that has not already been made public. Statements by army officers show, they say, that while training machines have been going over and many fighting planes have been made in France by American mechanics from American material, only about twenty-five American-made fighting aeroplanes will be delivered in France by July 1 instead of about 12,000, as proposed under the original program.

Two fighting planes had been shipped to France, the witness told the committee, according to the New York *Times,* fourteen more were ready to be sent abroad, and about a dozen others were in the final stages of construction and should be ready for shipment shortly. Fighting machines sufficient to compose three squadrons of eighteen machines each have been constructed in French factories from American materials and by American mechanics sent abroad for that purpose.

Statements made on the floor of the Senate that the Liberty motor so far has been used only in bombing machines, and other planes which do not need the extraordinary speed of the little single-seated fighters, are understood to have been confirmed by the witnesses, though they praised the work of the motor.

Members of the Military Committee will again visit the War Council at the War Department. It is understood they are not inclined to investigate charges made in the Senate by Senator Overman of North Carolina that there are spies in the Curtiss plant. Chairman Chamberlain said that it was a matter to be handled by the Department of Justice.

Publication of misleading statements regarding progress on the aircraft programme in the Official Bulletin issued by the Committee on Public Information caused a bitter arraignment in the Senate.

The material printed in the bulletin which aroused the Senatorial wrath had been condemned by the Senate Military Affairs Committee. It appeared in a photograph caption sent out to newspapers several days ago in which is was stated that "hundreds of aeroplanes have already gone to France and thousands upon thousands will soon be ready."

As against this statement, the Committee on Military Affairs discovered only one 'plane has been sent over. An investigation to establish the source of the caption writer's information was begun, and Lawrence Rubel, director of the division of pictures of the Committee on Public Information, who was called as a witness, admitted the information was misleading, and when the committee voted to request it be withheld from publication gave the body his pledge it would be suppressed.

Despite the pledge that the captions would be withdrawn from newspapers to which they had been sent and would be suppressed entirely, they were inserted in the Official Bulletin.

CURTISS GRANTED FLYING BOAT PATENT

THE United States Patent Office granted on February 19, 1918, the claims made in an application filed on December 11, 1914, by Glenn H. Curtiss, the well-known aeroplane constructor of Hammondsport, on behalf of a patent covering the construction of stepped and V-bottomed flying boat lulls. The specifications and claims follow in full.

To all whom it may concern:

Be it known that I. **Glenn H. Curtiss**, a citizen of the United States residing at Hammondsport, in the county of Steuben and State of New York, have invented certain new and useful Improvements in Hydro-aeroplane-Boats, of which the following is a specification.

My invention relates to hydroplane boats of the type commonly used in connection with hydro-aeroplanes of the flying boat type. It has for its objects the enabling of the craft to rise quickly from the water with maximum load aboard and having risen from the water to enable operation in the air with a minimum of head resistance due to the body of the boat. To these ends the main flotation body of the boat is given a longitudinal section of approximately stream line form, and a transverse section increasing in size from the head of the boat to a maximum approximately one-third length astern, and thereafter gradually decreasing in cross section until the tail of the boat is reached. This cross section is approximately the shape of an ellipse with one or both ends or sides cut off to form the bottom of the boat, or the top thereof, as the case may be. Further I decrease the minor axis of the ellipse more rapidly than the major axis as the cross section is decreased in the immediate vicinity of the tail of the boat, so that the section becomes substantially a straight line terminating in the vertical rudder post. Previous to this, the separate axes are independently varied in the rearward progression of adjacent cross sections to obtain the streamlines with which the boat is characterized, and to bring out to the fullest extent the features of efficiency above enumerated. The bottom of the boat is stepped and the front portion thereof constitutes the active hydroplaning surfaces, while the rear portion thereof underlying the tail proper makes a salient angle therewith. Preferably the hydroplaning bottom is V-shaped. On the sides of the boat are formed excresent structures the bottoms of which are in continuation of the hydroplaning bottom of the boat and the longitudinal section of which is of streamline form. Preferably these excrescent structures are water tight, and are of an approximately triangular section.

In the accompanying drawings, I show one embodiment of my invention but wish it understood that as usual in the case of an invention of this character, my invention is capable of many other embodiments without departing in any wise from its generic spirit.

Of the drawings Figure 1 is a side elevation of the boat of my invention.

Fig. 2 is a plan thereof.

Fig. 3 is a front elevation thereof showing aerial supporting surfaces attached and

Figs. 4 to 10 inclusive are transverse sections on lines 4 to 10 of Fig. 1.

10 designates the flotation body of the boat. As clearly indicated in the side elevation and plant of Figs 1 and 2 this body has a longitudinal section approximately stream line in form. There are a few slight irregularities in its surface, but these are insufficient to detract from the behavior of the boat in air as a streamline body. The principal variation is at the head or prow of the boat, where the top is cut straight back on the line 11 to form a front deck, and give unobstructed vision from the cabin 12. To complete the elevational stream line the cabin roof line would naturally be downwardly curved to round off into a substantially elliptical juncture with the nose. This forward elevational stream line, however, is interrupted by the provision of the fore deck 11 which extends horizontally and rearwardly to an intersection with the cabin, a cockpit being provided at the intersection of this deck with the cabin and a conning top having windows set therein being furnished to inclose this cockpit and to round off the interrupted lines of the cabin forwardly. The side and top walls of the cabin merge into the stream line of the body aft as indicated in Fig. 1. Entrance to the cabin is by a hatch door 13 in the top and preferably located beneath the upper aerial supporting surface whereby it is shielded from the weather.

The transverse section of the body of the boat is in the form of an ellipse cut away in some cases at opposite ends of an axis and in other cases at one end only. The section at the front of the boat as clearly shown in Figs. 4 to 7 is in the form of an ellipse cut away at each end of an axis, while the section at the tail of the boat as shown in Figs. 8 to 10 is in the form of an ellipse cut away at the lower end of one axis only. In the form shown this axis is the major axis, all of the major axis lying in the longitudinal vertical plane of the body. The cross section increases gradually to a maximum approximately one-third way astern, and thereafter decreases gradually. Both axes decrease proportionately for a part of the rearward distance traversed, then the major axis is shortened at the more rapid rate and finally the decrease of the minor axis of the elliptical section is made more rapidly than that of the major axis. These three successive stages clearly appear from inspection and comparison of Figs. 7-8, Figs. 8-9 and Figs. 9-10 respectively, the elliptical section eventually becoming a straight line in the rudder post 14. In other words the transverse section may be described as varyingly elliptical, the size of the ellipse (rearwardly from the prow) passing through successive stages in which (*a*) the major axis increase rearwardly, more rapidly than the minor axis (*b*) both axis decreasing rearwardly, and (*c*) the minor axis decreases at a more rapid rate than the major axis, the said sectional ellipsese terminating in a straight line at the rudder post.

The bottom of the boat is stepped as indicated at 15 (Fig. 1). The front portion thereof is of V section the angularity of which increases gradually from the stem 16 to the step 15 as indicated clearly in Figs. 4 to 7. Also it will be observed there is an abruptly increasing and then a gradually decreasing concavity of the opposite sides of the V-bottom merging into the substantially flat salient surfaces at the step 15. It will be observed, however, that this concavity is not great in any case, and further that the downward and rearward inclination of the bottom at the keel 17 is substantially the same as that at the chimes 18, excepting at the upwardly inclined prow of the boat which portion of course has no hydroplaning function.

Projecting laterally from the sides of the flotation body 10 at or near the chime lines 18 are elongated excrescent structures 19. These structures have an approximately stream line form as clearly appears from Figs. 1 and 2. Transversely they are of approximately triangular and varying cross section, one side of the said section being in continuation of the transverse section of the bottom of the boat (see Figs. 6 and 7), whereby their under surfaces constitute continuations of the main hydroplaning services, another side conjoining the sides of the main body 10, and the third side extending downwardly and latterally therefrom. Considering the conjoint sides of the hull and fin excrescences as identical, as is usually in the preferable construction, it will be observed that the fins in cross section then become of an acute V-shape, one side of the V lying in the plane of the bottom and the other side intersecting therewith from the hull. These excrescent structures 19 are made watertight independently of the main body 10 and in the embodiment shown are each hermetically sealed. The two structures 19 and the front portion of the main body 10 make a total of three longitudinally extending watertight compartments. The front portion of the main body 10 is further transversely subdivided into watertight compartments as indicated by the dotted line bulkhead 20. The tail portion of the boat is also divided into watertight compartments by transversely extending bulkheads 21.

Aerial supporting surfaces 22 extend laterally from the body 10 as indicated. In the preferred form of my invention, there are provided a multiple number of these surfaces in superposed relation constituting the cell of a biplane or triplane as the case may be.

The fins 18, it will be observed, extend considerably beyond the center of the wings and therefore the hydroplaning area and lift is augmented in the neighborhood of the center of gravity and center of pressure as it should be. This location of the fins 18, although most effective, after having gained the surface of the water, is of little importance in gaining this end. More important is it that the fins should be located in the vicinity of the resultant center of hydroplane lift so that the hydroplane lift will be increased at the point where it is most needed to be increased and at a point providing for quick rise from a submerged position at rest to a hydroplaning position upon the surface of the water at speed. The great advantage in so locating the fins is that the enormous thrust value occasioned by the elevated location in the motorer motors (not shown) is offset and the boat prevented from nosing under when coming to a hydroplaning position and when hydroplaning—especially when traveling at comparatively slow speed. In explanation, it is to be noted that three working forces are in evidence, to wit: gravity, thrust and hydroplane lift. Unless the hydroplane lift is sufficient to counteract the force of thrust, then the boat will have a tendency to plane with its nose low in the water. Were the fin excrescences omitted, the size of the fore body of the hull would have to be materially increased so that the hydroplaning area might be proportionately enlarged. This is objectionable because of the added weight and increased resistance during flight. The resultant center of hydroplane lift is shown by calculation to lie approximately one-third back of the forward end of the hydroplaning surface.

With this understanding of the structural embodiment of my invention, it will be clear that I have attained the objects thereof. The extended and very large hydroplaning surfaces provided by the bottoms of the excrescent structure 19 in conjunction with the main body 10 are of sufficient size to enable the body to come rapidly to its hydroplaning position and to rise from that position into the air with maximum load. In a recent trial, over a ton of useful load was lifted from the water in a run upon the surface not exceeding five hundred feet. The flying boat took to the air with great ease. As the head of the boat is pointed upwardly for the craft to take to the air, the tail, which until then is clear or substantially clear of the water is carried downwardly into contact therewith, the boat being as it were rocked about the step 15 as a

FIG.1.

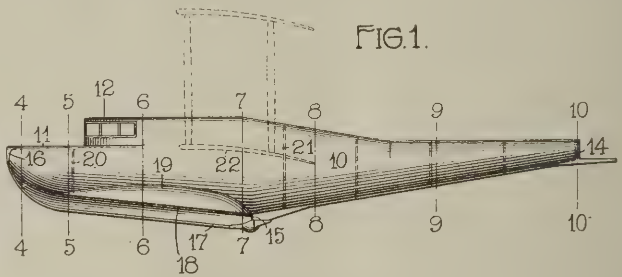

FIG.2.

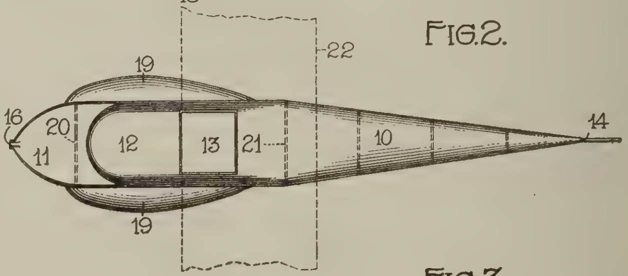

FIG.3.

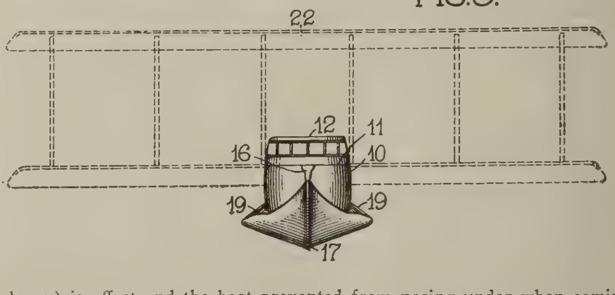

pivot. This assists in enabling the boat to rise easily from the surface of the water by reason of the increased flotation and additional planing surface provided at the critical point in the operation. When the craft is in the air, the longitudinal stream line formation of the excrescences 18 prevent them from materially increasing the head resistance of the boat. Under actual flying conditions it was found that they produced no noticeable retarding effect. Of course, the longitudinal streamline section of the body as a whole is productive of the same excellent results obtained in prior flying boats of my invention.

While on the surface of the water (or in the air for that matter), the operator has an excellent footing on the flat deck 11 and its form and location are especially adapted for the mounting and operation of machine guns for military purposes. The operator further has at all times unobstructed vision ahead directly over the flat deck 11, which forwardly mutilates the generating boat line of the cabin which would normally round off into the nose of the body.

The sealing of the excrescent structures 18 independently of the main body 10 gives to them the additional and very important function of watertight compartments. They are located at a point where these compartments are very much needed, directly opposite the cabin 12. It is of course not practicable to seal the cabin section. The flotation of this section of the boat is thereby materially raised and is assuredly of sufficient value under all conditions of service.

I claim:—

1. An aeroplane body comprising a main flotation body, the bottom of which is shaped to form hydroplane surfaces, and forwardly located marginal excrescent structures on the sides of said main flotation body, the bottoms of which are coextensive with and in continuation of the hydroplaning surfaces of said bottom.

2. A hydroplane boat comprising a main flotation body, the bottom of which is shaped to form hydroplaning surfaces, and marginal excrescent structures on the sides of said flotation body, extending longitudinally substantially the full length of said hydroplaning surfaces and having their bottoms in continuation of said hydroplane surfaces.

3. A hydroplane boat for hydroaeroplanes comprising a main flotation body, the bottom of which is shaped to form hydroplaning surfaces, and forwardly located excrescent flotation structures of triangular cross section on the sides of said main flotation body opposite the resultant center of aeroplane lift, one side of said section being in continuation of the transverse section of the bottom of the boat, another side parallel to the side of the main body, and the third side extending laterally and downwardly from a point on the side of the boat intermediate the chime and the gunwale.

FIG.4.

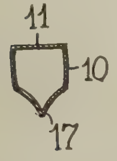

FIG.5.

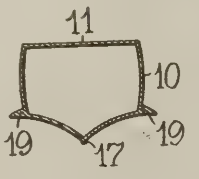

FIG.6.

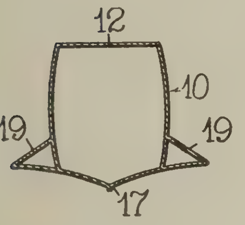

FIG.7.

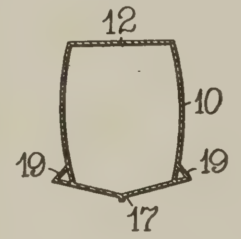

FIG.8.

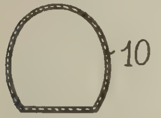

FIG.9.

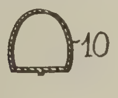

FIG.10.

4. A hydroplane boat body having an interior water-tight space for occupancy by the flying crew or other useful load together with watertight fin excrescences arranged to flank said space in the vicinity of the bottom of the boat, the excrescences conjointly functioning as planing surfaces and as lateral watertight compartments protecting said space.

5. A hydroplane boat body having an interior watertight space for occupancy by the flying crew or other useful load together with watertight compartments respectively ahead of, aft of, and at each side of said space, the side compartments being in the form of fin excrescences arranged to extend out laterally from the boat body proper to augment the hydroplaning area thereof.

6. A flying boat adapted to travel upon the surface of the water, rise therefrom and travel through the air, comprising a hydroplaning bottom surface laterally extended beyond the plane of the gunwales of the boat body proper by fin excrescences arranged at opposite sides of said body principally ahead of the center of gravity of the craft, the corresponding surfaces of said excrescences making a dihedral angle with the vertex thereof in the vertical plane of the keel line of said boat.

7. In a hull for flying boats, a V-shaped hydroplaning bottom and acutely V-shaped planing fins, each fin having one side formed in the plane of one of the V-sides of the bottom.

8. In a hull for flying boats, a V-shaped hydroplaning bottom, integral continuations of said bottom forming surfaces projecting beyond the hull and second surfaces projecting from the sides of the hull for intersection with the first said surfaces.

9. A flying boat including a main flotation body having a hydroplaning bottom, and fin excrescences arranged to augment said bottom laterally in the vicinity of the resultant center of hydroplane lift as determined through hydroplaning action on the surface of the water and preparatory to flight.

10. In a hull for flying boats, a V-shaped hydroplaning bottom and auxiliary planing fins formed as lateral extensions of said bottom, said fins being enlarged rearwardly from the bow of the hull in directions providing longitudinal and transverse stream lines.

11. In a flying boat, a hull rounding off rearwardly from its bow to provide a hydroplaning bottom and rounding off oppositely to provide a cabin situated over said bottom, and a fore deck for the hull intersecting the generating hull lines for the cabin.

12. A hull for flying boats enlarging rearwardly along rounded, upper and lower longitudinal hull lines, a hydroplaning bottom for the hull merging into the lower hull lines, and a deck intersecting the upper hull lines for provision of a cabin over said bottom.

13. In a flying boat, a hull, a cabin having streamlines merging integrally into the hull in one direction and a conning top rounding off the streamlines of the cabin in the other direction.

14. A hull for flying boats having its elevational aspect determined by lines rounding off rearwardly both upwardly and downwardly from the nose of the hull, and a deck intersecting the said upper boat line and cutting down the hull to provide a cabin.

15. In a hydroplane hull, an overhanging bow having an elevational aspect determined by lines rounding off rearwardly and downwardly, a bottom V-shaped in cross section, the angled portions of the bottom having their inception at the bow and considerably above the water line, each portion being decreasingly concaved from the nose rearwardly and the angle between the portions rearwardly, approaching a maximum obtuseness, and a step terminating said bottom.

16. In a hydroplane hull, a fore-body, a tail, a planing step dividing the bottom of the fore-body from the tail bottom, an upper surface for the tail enlarging forwardly in a reverse curve over said step and a cabin roof provided over the fore-body in advance of said step and merging into said enlarging tail surface.

17. In a hydroplane hull, a fore-body, a tail, a planing step dividing the bottom of the fore-body from the tail bottom, an upper surface for the tail enlarging forwardly in a reverse curve over said step to form a cabin roof for the fore-body and a deck intersecting said fore-body at a distance below said roof and destroying a normal merging of the roof line into the nose of the hull.

18. In a hydroplane hull, a fore-body, a tail, a cabin provided for said fore-body and having a roof merging rearwardly into said tail and forwardly into the nose of the hull, a deck intersecting the cabin and a cockpit provided at the intersection of said cabin and deck.

19. A flying boat including a flotation body having an underneath hydroplaning surface of a size in cross section designed to extend out on either side beyond the boat body proper approximately opposite the center of hydroplane lift, the bottom surfaces of the laterally extended portions making a dihedral angle with the vertex of the angle in the vertical plane of the keel line of the boat.

20. A flying boat including a main flotation body having an underneath hydroplaning surface of substantially V-form in transverse section, fin excrescences arranged to augment the hydroplaning surface laterally in the vicinity of the resultant center of hydroplane lift, the bottom surfaces of the fins continuing uninterruptedly the hydroplaning bottom of the boat body proper.

21. A flying boat including a main flotation body, a hydroplaning under surface, and lateral extensions of a construction designed to conform longitudinally to said hydroplaning under surface and to extend substantially the full length thereof.

22. In a hydroaeroplane boat body, a bottom longitudinally convexed, and auxiliary planing surfaces formed as lateral extensions of said bottom in the vicinity of the resultnt center of hydorplane life, said center lying considerably in advance of the point of maximum convexity, and sufficiently distant therefrom to provide for its movement rearwardly to a point in the vicinity of said point of maximum convexity upon fore and aft oscillation of the boat.

23. In a hydroaeroplane boat body, a bottom longitudinally convexed, aeroplane wings extending intermediately across said body, the point of maximum convexity underlying said wings, auxiliary planing surfaces formed as lateral extensions of said bottom, said surfaces commencing in advance of the resultant center of hydroplane lift and terminating rearwardly in the vicinity of said point of maximum convexity.

24. In a flying boat, a main flotation body, a hydroplaning under surface, fin excrescences coextensive with the hydroplaning surface, each fin extending forwardly beyond a line in the vertical plane of the resultant center of hydroplane lift a greater distance than to the rear thereof.

25 A flying boat including a forward hydroplaning bottom designed to extend from end to end uninterruptedly and at an angle laterally beyond the sides of the boat body proper to materially increase the hydroplaning surface and enable the boat to come rapidly to its hydroplaning position upon the surface of the water and to rise from that position into the air.

26. In a hydroplane boat, a bottom longitudinally convexed, and auxiliary planing surfaces formed as lateral extensions of said bottom to extend substantially to the full length of that portion of said bottom ahead of a point determining the maximum convexity thereof.

27. In a hydroaeroplane flotation body, a longitudinally convexed bottom in which that portion of said bottom in advance of the point of maximum convexity is of hydroplaning form, fin excrescences arranged to augment said bottom laterally in the vicinity of the resultant center of hydroplane lift, aeroplane wings, the center of pressure on said wings being disposed in the approximate transverse vertical plane of said point of maximum convexity, and said point determining the rearward terminus of said fins and the rearmost point to which the center of hydroplane lift may be shifted as the body in its entirety is oscillated fore and aft.

In testimony whereof I affix my signature in presence of two witnesses.

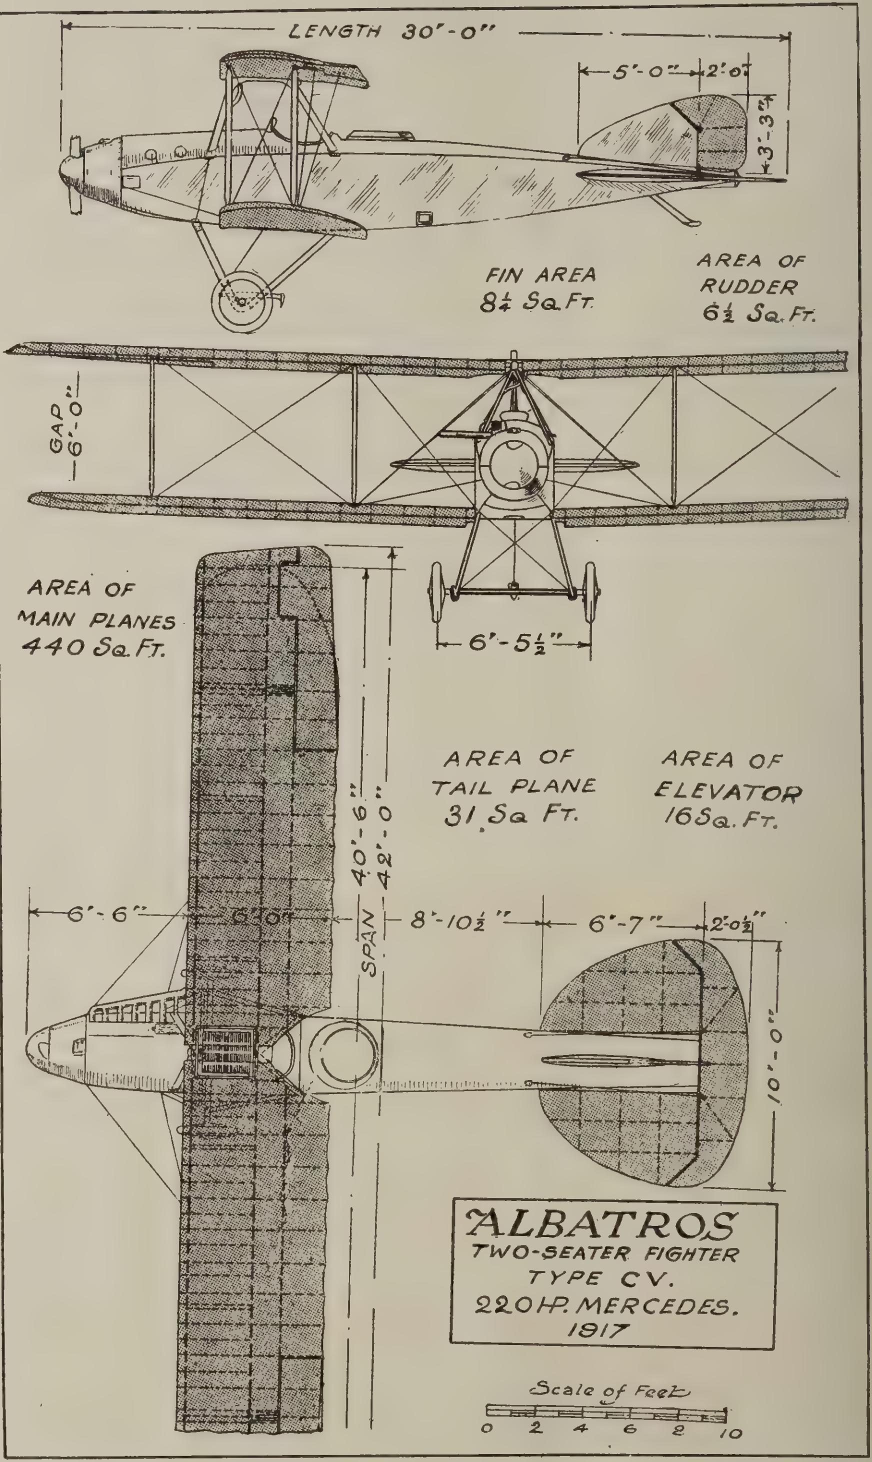
THE ALBATROS TYPE "CV" FIGHTER*



THIS Albatros biplane belongs to what is now commonly referred to as the "C" class—that is to say, a general utility machine used for artillery observation, reconnaissance work, photography and fighting. Incidentally the machine appears to be also used for bombing—in a small way only—as it is equipped with a bomb rack holding four bombs.

Aerodynamically the Albatros to be dealt with in what follows is, perhaps, chiefly interesting on account of the evident attempt on the part of the designer to provide as good a streamline body as is possible having regard to such external fitments as machine guns, etc., which naturally detract to a certain extent from the efficiency of the lines of a body of a modern two-seater, where the gunner frequently has to stand up, with the upper portion of his body projecting above the fuselage covering. This effort at streamlining is particularly noticeable in the nose of the machine, where the aluminium cowling over the engine is carried right across, leaving only the exhaust collector exposed. In front of the covering of the body proper is a cowl shaped as a truncated cone, which serves to enclose the nose and reduction gear of the engine, and to carry the lines of the body into those of the "spinner" around the boss of the air screw. The sides of the body, from a short distance behind this cowl to the tail, are flat, as is also the bottom, but the top of the fuselage is covered with a curved covering of three-ply.

At the rear the fuselage terminates in a horizontal knife's edge, an easy flow being provided for the air by running the top covering of the fin into the three-ply covering of the fin in a smooth curve. Similarly, the fixed tail plane, which is of a symmetrical section and very deep, has its top surface practically in continuation of the top covering of the body, presenting no great and abrupt changes in curvature. The total effect is one of extremely smooth and easy flowing curves, and the body resistance cannot be very great in proportion to the cross sectional area of the body. We have no figures of the actual resistance coefficient in the formula $R = k\,AV^2$, but are inclined to imagine that the coefficient k has quite a low value.

As regards the rest of the machine, the Albatros designer does not appear to have been so careful in cutting down resistance. For instance, the wings have the usual circular section stranded cables for taking lift and landing stresses, and no attempt appears to have been made at streamlining these.

Constructionally the Albatros shows much that is of interest, chiefly in the construction of the body, but also in other respects, as we hope to show in later instalments of this descriptive article. Fundamentally, the Albatros body construction is that employed in building light boats and hydroplanes. There is a light framework, consisting of four main rails at the corners of the rectangular section body, two auxiliary rails somewhere about half-way up on the sides, and bulkheads or transverse partitions of varying shape and thickness along the body at intervals. The whole is then, as in boat building, covered with a skin of veneer ply-wood, in this case three-ply. Regarded as acompromise, this form of body construction would appear to be quite good. Without entailing the time and expense of the true *monocoque* body, it provides a reasonably good streamline form. As a manufacturing proposition it is probably about equal to the girder type of fuselage, while it has the advantage of not requiring any trueing up in the erecting process, this following automatically when making the parts over jigs and formers. One advantage this form of body does appear to possess, although to a somewhat lesser extent than the true *monocoque*—shell splinders and rifle and machine gun bullets are less likely to damage it seriously than is the case with the girder type. In the latter, should a longeron be shot through nearly all the strength of the structure is gone, whereas this semi-*monocoque* structure would retain its strength even after damaging some of the longitudinal members.

Finally, there is the question of strength for weight. We have no data relating to tests of such a structure carried out by our own authorities (although possibly such tests may have been, and certainly should be, made. But in an issue of *Flight* of April 4th, 1914, there was published particulars of an Albatros biplane which was brought over to England and flown by Thelen, which had a body fundamentally similar to the one at present under discussion, although differing from it in minor details. At the time we were furnished with some particulars of tests carried out on an Albatros fuselage of this type by the *Deutsche Versuchsanstalt für Luftfahrt*, according to which the factor of safety of the Albatros body was about 60, and the resistance to bending 2.5 times greater than that of a diagonally wired fuselage of the same outside dimensions, and having members of the size usually employed in structures of this type. The *Versuchsanstalt* also stated that the Albatros firm

---

*Courtesy of *Flight*, London.

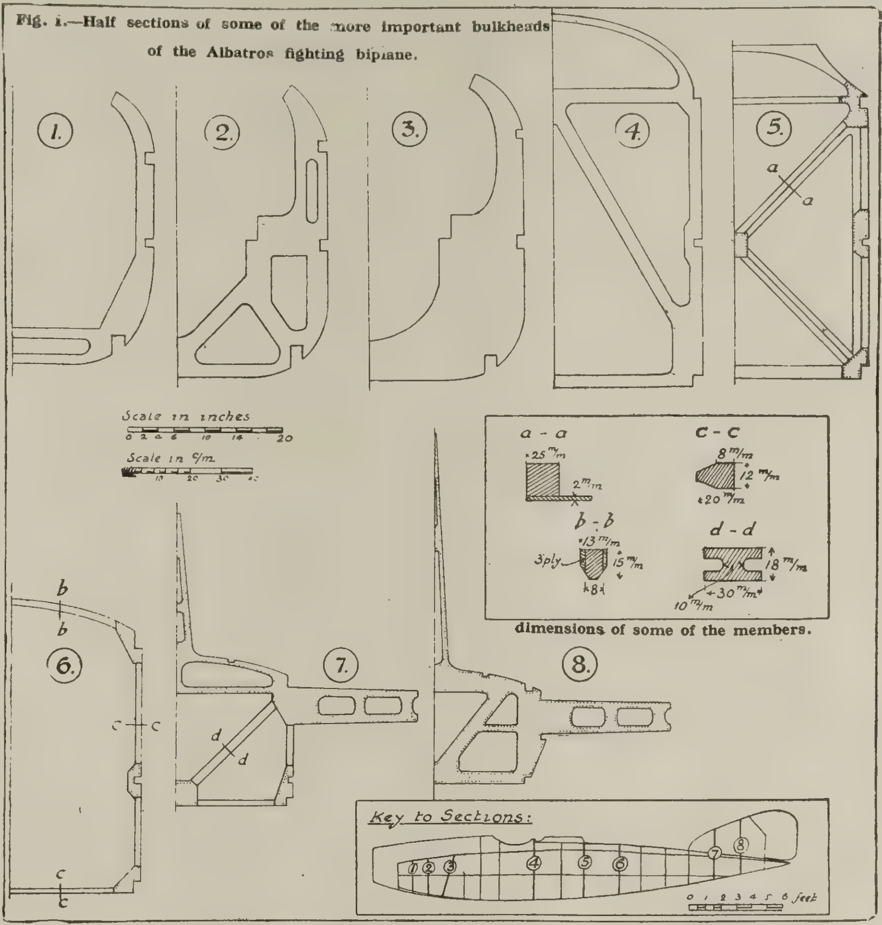
were justified in concluding that the bending resistance of the veneer type of body is greater than that of a cross wired fuselage of the same weight, although no actual figures were given showing how much greater.

When looking into the detail construction of the Albatros body the first thing that impresses one, apart from the absence of internal cross bracing, is the extensive use that has been made of veneer in the construction of the transverse bulkheads or formers, which take the place of the struts and cross members of the girder type of body. In Fig. 1 are shown the different bulkheads of the body, with dimensions, etc. The rail half-way up the sides of the body is placed parallel with the propeller shaft, thus serving as a datum line from which to make measurements of distances and angles.

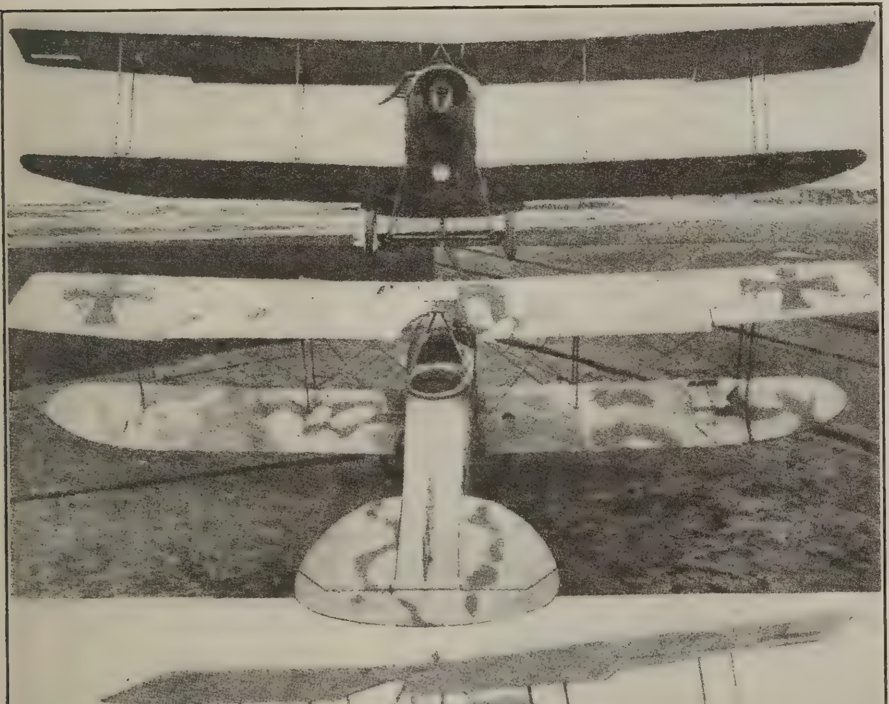
In order to enable our readers to better form a conception of the Albatros construction we have shown, in Fig. 1, half-sections of the more important and representative bulkheads. In the front portion of the body the bulkheads, which here have to take the weight of the engine, are about 1¼ in. thick, and are made up of a number of laminations of wood, which are, of course, so placed in relation to one another that the grains of adjacent layers run at angles to one another. It was further noticed that in making up these bulkheads whole sheets of the different woods were not always employed. On the contrary, many of the layers appear to have been shouldered or spliced, being made up of comparatively small pieces. It is possible that this has been done with a view to utilizing pieces of wood that would otherwise have had to be scrapped. On the other hand, it may have been done to increase the amount of crossing of the different grains. In any case, it would appear to serve both purposes, although one would expect the time taken in manufacture to be somewhat increased by such careful fitting together of small pieces of wood.

Fig. 2 shows the nose of the Albatros, and clearly indicates the method of supporting the engine. The first bulkhead, it will be seen, is solid, and is at right angles to the propeller shaft. The second bulkhead—2, Fig. 1—is lightened by piercing as shown, and is also vertical, while the third engine support is formed by a solid bulkhead—3, Fig. 1—which slopes back so as to support the front chassis struts and front cabane struts at its lower and upper ends respectively. As the front engine support is clearly shown in the sketch, Fig. 2, it has not been included in Fig. 1. The bulkhead numbered 1 in Fig. 1 is merely a former, and does not help to support the engine bearers. These are of I-section spruce, and have plywood flanges top and bottom as shown in Fi.g 3. The upper flange is continued outwards to the middle longeron so as to form a shelf or bracket at the sides of the engine.

Fig. 1.—Half sections of some of the more important bulkheads of the Albatros fighting biplane.



dimensions of some of the members.



Three views of the Albatros "CV" Fighter.

A construction somewhat different to that of the engine supports is employed in the panel between the pilot's and gunner's cockpits. This consists (4, Fig. 1) of a spruce framework faced each side with 3 mm. three-ply, the whole having a thickness of 26 mm. (about 1 in.). Behind the gunner's cockpit is a light partition built up as shown in 5, Fig. 1. Two light spruce struts run diagonally across from corner to corner of the body, crossing in the center of the fuselage at which point they are reinforced by three-ply facings and triangular blocks glued into the corners.

Their attachment to the upper and lower body longerons is of a similar construction, and will be clear from the diagram. On their front faces these diagonal struts are provided with a 2 mm. flange to stiffen them against buckling. A canvas curtain is secured to the front of this partition, having in it pockets for maps, etc.

From this point back to the front where the tail plane and vertical fin are attached the formers of the body are in the nature of a very light framework of thin struts, a typical one being shown in 6, Fig. 1. The general construction and some of the dimensions of the various members will be clear from the illustration.

One of the features in which the present Albatros differs from previous types is the construction and attachment of the tail plane and vertical fin. The latter is covered with three-ply, and is made integral with the body, out of which it grows, so to speak. The construction is shown in 7 and 8, Fig. 1, and in the perspective sketch, Fig. 4. The tail skid is supported on one and sprung from the other of these two bulkheads, as illustrated in Fig. 5 (see page 227), the general and detail construction of it being evident from the sketches. The tail plane is provided with hollow spars which fit over cantilever beams integral with bulkheads 7 and 8, Fig. 1, the details of which arrangement will be dealt with later.

Having dealt with the bulkheads or transverse partitions of the Albatros fuselage, the longitudinals rails will be considered next. These are of a somewhat complicated nature, varying as they do along their entire length, not only as regards being tapered from front to rear, but also in the different form of spindling out employed at the various points, and in the method of reinforcing with other strips of wood, partly in order to increase their strength where required and partly to make their overall section conform to the various angles and curvatures of the outisde three-ply covering of the fuselage.

From Fig. 6 a fairly good idea may be formed of the shape and dimensions of the longerons at various points. The lower one (left hand) is originally of rectangular section, but is lightened from point to point by various forms of spindling and stop-chamfering. Thus at the point B (see key, diagram Fig. 6), the inner face of the bottom longeron is spindled out on its inner face with a curved cutter. At other points of this longeron farther towards the stern various sections are met with, as channel, solid rectangle, and L sections of various proportions. Between the horizontal stern post and the point at which the middle longeron meets the lower one, the latter is reinforced with a triangular section strip, so as to carry the three-ply covering into the sloping side. Similarly at the section A, Fig. 6, the longeron, which is here of solid rectangular section, is reinforced on the outer side with a curved trip, spindled out externally, and with a smaller strip on the lower face of the longeron. This is done partly to strengthen the longeron, which at this point is subject to an increased compressive load, owing to the overhung engine, and also to afford attachment for the three-ply covering, which at this point changes from flat sided to rounded section where the sides gradually merge into the truncated cone of aluminium which forms the extreme nose of the body proper *i. e.*, at the point just behind the "spinner" on the air screw boss.

The upper longeron, which is originally of rectangular section, is spindled out to channel and L sections at various points, as shown in X, Y, Z, Fig. 6. So as to form an attachment for the curved top of the body, the top longerons have glued to their upper face additional strips of triangular section while at the point Y, Fig. 6, the section is left rectangular so as to form a support for the gun ring. In addition to their function as strengthening members these strips serve the further purpose of preventing the bulkheads from sliding along the longerons, as they are cut off where a bulkhead occurs, against the front and rear sides of which they abut. In some places, as for instance in the front of the body where the covering is in the form of an aluminium cowl over the engine, the strips are omitted and the cowl attached to turn-buttons as shown in the sketch Fig. 7. At such points the bulkheads are prevented from sliding along the longerons by a long wood screw passing horizontally through the longeron into the bulkhead.

The middle longerons, which, as already pointed out in a previous article, are horizontal, *i. e.*, parallel to the propeller shaft, are of smaller overall dimensions than are the four main longerons. They are rectangular section, lightened in places by stop-chamfering, as shown in *a* and *b*, Fig. 6.

BUREAU OF STANDARDS TEST AVIATORS' GOGGLE GLASS

THE Bureau of Standards recently completed a series of tests on non-shatterable glass suitable for aviators' goggles. The following is the official report:

Nature of Report

"This report deals principally with the so-called non-shatterable glasses intended to protect the eyes from splinters when accidents occur which fracture the glass used in spectacles, aviator goggles, face masks, windshields, etc.. Some of the optical properties such as transparency and distortion will also receive consideration.

Description of Material

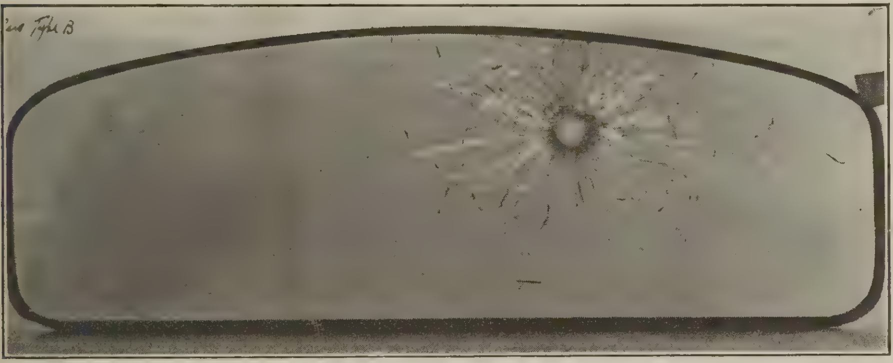
"The material covered in this report consists of two types of protected glass in one of which (A type) the glass has one side covered with a layer of celluloid, and in the other (B type) a layer of celluloid is sandwiched between two layers of glass.

Plan of Investigation

"Comparative values of the dynamic strength and shatterability of the glasses were obtained by subjecting the glasses to sudden shock or impact either by dropping a steel ball on the glasses or by shooting a bullet at them.

Test No. 1

"The glass was fastened on top of a block of wood covered with ¼-inch rubber with a 1½-inch hole in the center. A steel ball weighing 4 ounces was dropped on the surface of the glass from increasing heights until rupture occurred and then *additional blows* were delivered from this last height until the glass was powdered.



Result of 30 caliber bullet with muzzle velocity of 2700 ft. sec., fired at Type B Resistal glass at distance of 25 yards. See report.

Results

All the glasses listed above are of type B except those designated G.F., which are type A. The fracturing blow developed many cracks radiating from the point of impact, but the lens as a whole remained intact and lost no splinters.

"The last column shows the number of blows required to powder the glass above the celluloid film. The B type glasses, in general, lost no splinters from the rear surface until the front surface was completely shattered and the steel ball struck the intervening layer of celluloid. Column 4 there, represents the number of blows delivered to the B type glasses before splinters flew from the rear of the glass.

"The A type glasses lost no splinters from the under surface, as this surface was the one covered with celluloid.

Test No. 2

"A 30-caliber bullet with a muzzle velocity of 2700 ft. sec was fired from a distance of 25 yards at a target supporting the glass. Plates of glass (about 4 x 10 inches) were held firmly against rubber strips on the target.

Results

"Type A glasses received a ragged hole and were so badly shattered over the entire area that vision through the glass was greatly impaired. Although the celluloid film continued to hold most of the pieces of glass together, very little rigidly remained in the plate.

"A bullet passing through type B glasses made a clean cut hole and produced numerous irregular cracks in each of the sheets of glass separated by the celluloid. These cracks were confined to a circular area of about 2 inches radius and the remainder of the plate remained practically uninjured. The cracks in the two plates of glass separated by celluloid in general, followed different directions, and did not register. The fact allowed the laminated plate to retain considerable rigidity even after it had been punctured. All the glass except a small area immediately around the bullet hold was firmly held by the celluloid.

"Ordinary plate glass, without celluloid covering, when struck by the bullet, flew into innumerable pieces and became a complete wreck.

"The effects of bullet penetrations on types A and B glasses are shown in the attached photographs.

Conclusions

"Glasses of type A, with an exterior coating facing the eyes, will protect the eyes from glass splinters unless the coating is ruptured. A coating of celluloid, however, is very unsatisfactory for several reasons.

"The samples examined were not evenly coated, and distorted vision a great deal, especially near the edges.

"Celluloid is comparatively soft and would soon lose much of its transparency if exposed to weathering and scratching.

"Glasses for spectacles, goggles, and face masks, should be of material which may be sterilized by immersion in boiling water. Such treatment makes celluloid opaque and also removes it from the glass plate.

"If satisfactory coating substances can be found, such covered glass should be of value in shielding the eyes and face from splintering glass.

"Laminated glass, or type B, when made with good glass, produces very little distortion.

"Glass plates on either side of a transparent layer of binding material protect this material from weathering or scratching. Celluloid, however, is not a very satisfactory substance to put between glasses. Unless the edges are permanently sealed, such glasses are apt to be discolored or ruined by immersion in sterlizing baths. Some of the samples reported on above had sealed edges, but the seals were not highly resisting or permanent.

"The transparencies of type B samples which were actually measured were found to be only fair. From 80 to 86 per cent of the total incident light was found to be transmitted by these glasses. Better quality glass and a more transparent inter layer would reduce the absorption of light.

"The relatively increased non-shatterability of laminated glass and its comparatively good transparency and rigidity even after puncture, give it great importance in devices for protecting the eyes and face."

To End Profiteering in Officers' Equipment

A bill is under consideration of the House Committee on Military Affairs providing for the sale of army officer's uniforms at cost price. Tailors and uniform makers have been overcharging, so that the cost of the required equipment greatly exceeds the allowance made to officers tor the purpose. The elimination of this form of profiteering will be welcomed, and if the increased cost of materials accounts for the very materially increased prices of clothing their sale by the Government will very likely result in raising the allowance to officers for the purchase of uniforms and equipment.

Another form of profiteering—that of unduly raising the rent in districts where Government employees are forced to reside by the nature of their duties—is also to be eliminated by a bill now in the hands of one of the Congress committees.

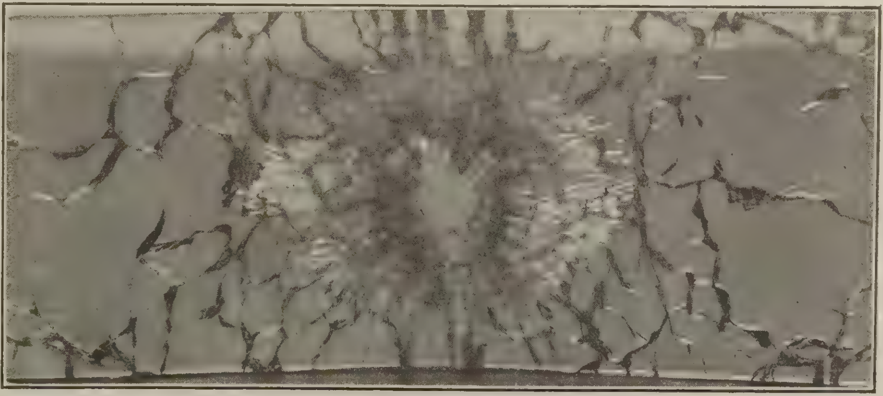
England and America

For their respective first three months in the American War Savings Campaign is running ahead of the English campaign. America is pouring into the Treasury at the rate of about $2,000,000 a day—over $75,000,000 up to date.

The direct comparison is:

	England	*America*
First month.........	$5,172,000	$10,236,451
Second month.......	2,719,000	24,559,722
Third month........	3,402,000	41,148,244
Total	$11,293,000	$75,944,417

The $75,944,417 of spending already put at the service of the Government by the buyers of war savings securities has transferred from millions of patriotic saving citizens to the National Treasury command of the labor and materials to build a fleet of about on hundred 5,000-ton ships.



Result of 30 caliber bullet with muzzle velocity of 2700 ft. sec., fired at Type A glass at distance of 25 yards. See report.

ENGINE WEIGHT

By F. W. LANCHESTER

It is commonly a fact that in order to obtain the highest possible fuel economy the weight of a petrol motor requires to be made greater than when economy is sacrificed. A question with which the aeronautical designer or constructor is frequently faced, in the adoption of an engine to form the basis of his design, is whether, for a given time or distance to adopt a light-weight engine having perhaps not the best possible fuel economy or a heavier engine in which the fuel consumption per h.p. hour is less.

The writer believes he was the first to make use of the now well-known h.p. weight diagram in which abscissæ represent hours of light and ordinates the gross weight of engine plus fuel and lubricating oil (Fig. 1). In such a diagram (Fig. 1, which is taken from the first report 1909/10 of the Advisory Committee for Aeronautics) it will be seen how the graph for the lighter engine, such as the Gnome, with its heavy consumption of petrol and lubricating oil, crosses the graph of one of the heavier and more economical engines at some definite point representing a certain number of hours' work at full load; when applied to the aeroplane this may be taken as some definite number of hours' flight. For military purposes it is common practice to-day to specify some definite period of flight and to give the weights of engines plus fuel, plus lubricating oil corresponding thereto; this, on the diagram, Fig. 1, is equivalent to reading the fuel values for some definite abscissa (time value) on the ordinate scale. In Fig. 1, for example, taking four hours as time of flight, the figures for the various engines given were (in 1909) as follows:

Gnome 50-h.p. (Aero Engine)	7.5
Antoinette (Aero Engine)	9.1
Renault 70-h.p. (Aero Engine)	10.3
Daimler 38-h.p. (Motor-car Engine)	12.3
Daimler 22-h.p. (Motor-car Engine)	13.0

In order to construct a diagram such as Fig. 1 we require to know the weights of the engines without fuel or lubrication, and the rate of consumption in each case. Alternatively, if the weights without fuel or lubrication be given, and the weights for any definite number of hours' flying, the diagram may then be immediately laid out. It will be seen that the diagram is the preferable method of comparing two engines, inasmuch as the performance for any given hour period may be compared, and is visible at a glance.

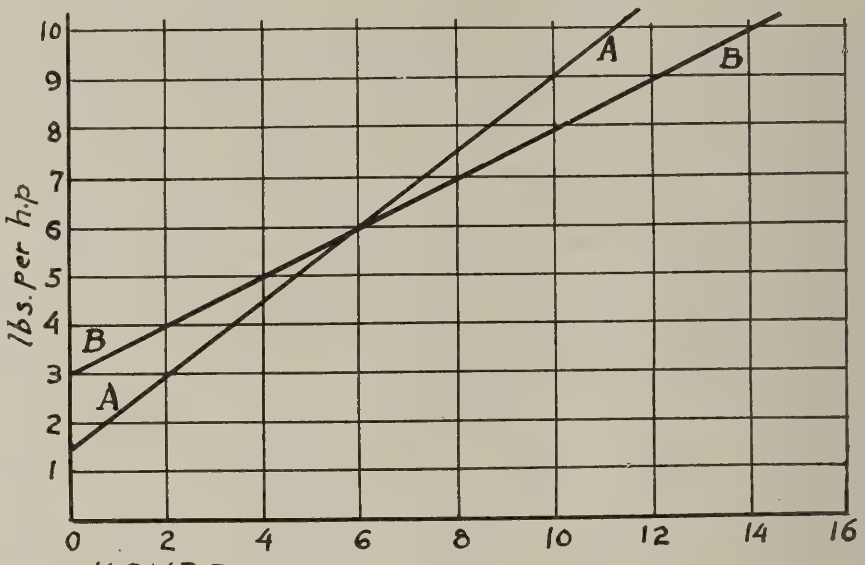


Figure 2

The object of the present article is to call attention to the results obtained if, in selecting an engine as suitable for given duty, circumstances other than that of aggregate weight, as represented by the diagram, be left out of account. There has, in my opinion, been too great a tendency to discuss the question of engine suitability from the point of view of aggregate weight alone, and to reply too implicitly upon the bare figures to the neglect of other considerations which are of no less importance. The plain and unvarnished fact is that to judge engines on their augmented weight, as given, for example, by Fig. 1, is equivalent to considering the performance of the aeroplane to which the engine is applied as that proper to it *when leaving its aerodrome*, or the starting-point of its flight, apart from its performance, probably some hours afterwards, when it is engaged with an enemy, or occupied in pursuing or evading pursuit. It is also no less important to consider the condition when the flight is over and when alighting.

When we remember how much importance attaches, in the design of a machine as a whole, to its permissible alighting speed, we realize how serious the neglect of this latter condition may actually be.

As a comparison and contrast let us take the imaginary case of two engines of 200 h.p. In case *A* let us assume that the engine weight be 1.5 lb. per h.p., and in the other case let it be 3 lb. per h.p., and let us assume that in case *A* the petrol and lubricating oil consumption be 0.75 lb. per h.p. hour, and in case *B* let it be 0.5 lb. per h.p. hour. Then on a comparison basis of six hours' flight we have the account as follows:

A.		B.	
Engine weight.	300	Engine weight.	600
Fuel weight....	900	Fuel Weight....	600
	1,200		1,200

Total—1,200 lbs. in each case.

Now, on the basis of the diagram, Fig. 2, these two engines are on terms of equality. What are the actual facts if two similar machines be fitted with engine *A* and engine *B* respectively? On their leaving the aerodrome (assuming propeller efficiencies, etc., the same) their performances, speed, rate of climb, etc., would be identical; but let us imagine that both, after two hours' flying—one-third of the whole period—to be engaged with the enemy. Aeroplane *A* has consumed 300 lb. weight of petrol, aeroplane *B* has consumed 200 lb. weight. *A* is 100 lb. lighter; its flying speed, its climbing capacity, and its height of ceiling will all be correspondingly benefited, and between the two machines in the air there will be no question as to which is the superior.

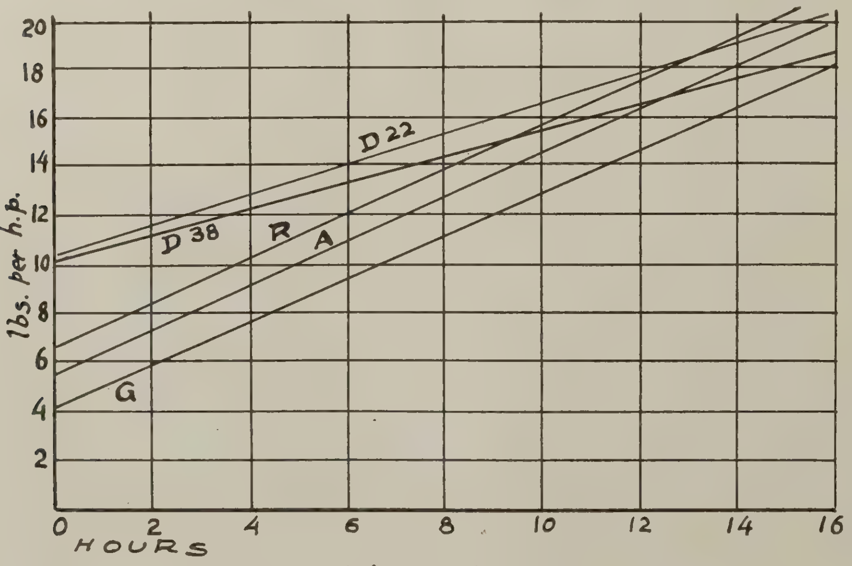

Figure 1

I have heard many men, who affect to take a practical view of the subject, say that as far as performance goes you cannot detect, in an aeroplane of, say, 25 cwt. or 30 cwt. gross weight, a difference of 20 lb. more or less, and who rather pooh-pooh weight save as being carried to an unnecessary point. It is certainly strange that such views should require answering, but in view of the quarters in which I have heard such opinions expressed, they certainly cannot be ignored. There are two lines of argument to convince that superior type of person who calls himself "practical." Parenthetically, it may be remarked that the man who boasts of his knowledge being "practical" is rather like a girl who, having an ugly face, says: "Look at my beautiful hair," when, after all, her hair is nothing out of the ordinary; or like the man who, having been born a cripple with no right arm, is very self-satisfied because he can manage to put his food into his mouth with his left hand. His peculiarity is not commonly any surfeit of practical ability, but an absence of theoretical training and of all capacity for exact thought.

One answer is that although 20 lb. cannot be detected in the performance of an aeroplane, *several 20 lb. items can*, which all goes to prove, not that 20 lb. does not matter, but that an aeroplane considered as a weighing machine is not an instrument of precision. Another answer which perhaps will appeal more to the "practical" man is that if a machine weighs 20 lb. less without sacrifice of structural strength, engine power, or any other of those things which count in its performance, then it can carry 20 lb. more of ammunition, bomb weight, or whatever it needs.

If, then, we consider the fighting machine we must be prepared to admit that the comparison between engine and engine must not be made with the full load of petrol for the flight period specified, but rather upon its average condition, when it may be presumed to be engaged with an enemy.

Commonly, it would be fair to put it that the criterion of engine weight for such duty should be about half the full fuel load and not the full load as has been too generally assumed. In other words, referring to Fig. 2, if the period of flight for which fuel and lubrication capacity is provided (and which is in contemplation) be six hours, the criterion on which the weight of the engine should be judged should be a period of three hours, and if the period be four hours the criterion period should be two hours. In the event of the straight-line graphs representing the two engines in question, intersecting between the half-flight period and the full-flight period so defined, the point of view taken in the present article would result in a reversal of the decision as to which engine is the most appropriate.

When we deal with the bombing aeroplane the same considerations apply with equal force, for the bombing machine would commonly have its roughest time with the enemy when nearing its objective, and when, say, one-third of its petrol has been consumed; and after leaving its objective, also during its return its height of ceiling and its speed of flight will be important factors in enabling it to get home without molestation.

But these purely military considerations are not alone. As already stated, the question of land speed is one of great importance. Here we may for all intents and purposes assume that the power weight factor of the engine itself is all that counts. It is true that there will always be a small reserve of fuel and lubricating oil at the finish, but this may, at a pinch, be jettisoned, and in any case it may be neglected for the purpose of discussion. Alternately we may assume, as a concession to the point, that the weight taken comprises half an hour's petrol and fuel supply. We know that the whole design of an aeroplane hinges on its alighting speed. If once the alighting speed is prescribed, a superior limit is set to the speed of least resistance, and the resistance graph is determined. The maximum speed of flight, then, is when the thrust line cuts the resistance graph. Without any advance in engine design this maximum will be increased if a higher alighting speed be permitted. The point under discussion is that if we take the admittedly extreme example of the two supposed aeroplanes *A* and *B*, when these are alighting after exhausting their petrol, aeroplane *A* weighs 300 lb. less than aeroplane *B*; 300 lb. may be taken as 10 per cent of the total weight, and will permit of a 5 per cent lower alighting speed, other things being equal. Consequently, machine *A* may be designed on the basis at full load of a 5 per cent higher alighting speed. Thus, disencumbered of its fuel, its alighting speed will be the same as aeroplane *B* in like condition. Under these circumstances the lighter-weight engine, relatively extravagant in fuel, although apparently on terms of equality from the point of view of total gross weight, will be in every way superior, machine for machine, to the heavier type. The lighter engine will give the designer scope to produce a machine outpointing the other in every important respect.—Courtesy *Flying* (London).

INDUSTRIAL DEPARTMENT

AEROPLANE CONSTRUCTION IN QUEENS

By FRANK E. BREYFOGEL

Industrial Manager, Chamber of Commerce of the Borough of Queens, N. Y. City

IN the Borough of Queens section of New York City, there are today 14 aeroplane and closely allied manufacturers at work on the production of finished planes for the government—engines, planes, propellers, bearings, moto-meters, aviaphones and other accesories. In addition there is one of the largest construction laboratories in the United States in which new models of war type aeroplanes are developed for the government under contract. An aeronautic station covering 100 acres is also established in this important section of New York City.

First Firm in the U. S. to Produce Rotary Engines

Long before the declaration of war by the United States, a firm in the Borough of Queens was manufacturing the rotary type aeroplane for the Allies. It was the only firm then doing such work and still remains the only one in the United States today.

Probably the experience and ability of this firm in the production of so intricate a type of mechanism with the necessary high-class labor that is required for such work is one of the potent reasons why the Borough of Queens has developed into an aeroplane production center.

It is common knowledge that when Great Britain entered the war, they found themselves under the weight of a veritable avalanche of orders calling for Gnome engines for the British air fleet. They turned to the United States, and although the specifications for manufacture were most exacting, one American concern in Queens Borough undertook the work and secured the rights to build and sell the Gnome and the Le Rohne engines.

It proved that the manufacturer of this type of engine, the most difficult of all aeroplane engines to produce—has been a successful enterprise in America. A large proportion of the pursuit planes and speed scouts that are used on the firing line on the European battle front, are equipped with the rotary engine.

Manufacturing Complete Planes

One firm in the Borough of Queens is and has been since making scout planes and has just begun the production of flying boats. While this plant now covers 75,000 square feet of floor space employing 600 men and producting on the average of 5 planes per week, an additional 200,000 square feet is now being constructed to be completed April 15th. When the addition is completed this firm expects to employ about 2,000 men and to at least triple their output.

Another concern is producing graduate training biplanes and equipping them with 160 H. P. motors.

Propeller Production of a High Order

A large producer of propellers has established a factory in the Borough of Queens employing 100 men and turning out at the present time propellers probably equal in number to the other propeller factories in the United States, in spite of the fact that at times they have had from 25 to 30 different types of propellers going through the factory at the same time. Propeller building includes the ability to design special work suitable for the very numerous types of machines which have been offered to the government for test purposes, as well as to meet a further condition, namely, the almost equally numerous types of motors.

The experience of this factory in locating in the Borough of Queens is interesting and is incorporated in the following statement of its president:

"It was no easy task last summer to locate a suitable factory for the purpose of manufacturing propellers. It was not until the middle of October that we finally moved into the building now occupied. Special machines were required, special tools. Anyone who in the last eighteen months has attempted to equip even a small plant will realize the cost of this in both time and money.

"The Borough of Queens has proved an excellent labor

The Borough of Queens offers many advantages to the aeroplane industry.

market with good delivery and shipping points. The local concerns who have been called upon to aid in the supply of material have given their full cooperation."

Other firms are engaged in the manufacture of propellers for the Government though the latter are not devoting their entire organization to this production alone.

Construction Laboratory in Queens Borough

One of the largest construction laboratories in the United States in which new models of war type aeroplanes are developed for the Government under contract is established in Queens Borough. This company has taken the customary type of aeroplane construction and very greatly reduced its weight, thus enabling the same machine to carry greater load or to make a higher speed. They have taken machines that were of very little use for military operations and so decreased the weight by improving construction, that instead of carrying one person they can now cary two, together with greater fuel and an increased number of bombs. This company now has contracts with the Army and Navy for advanced types of other machines.

They are working on the principle that simplification of construction is a function which calls for the highest engineering skill. They established their headquarters in the Borough of Queens because:

1. Of the availability of the highest type of skilled mechanics.
2. Because of the proximity to the port of shipment of the finished product overseas.
3. Because of the proximity of the Mineola flying grounds which are conceded to be among the best in the country.

Curvature of Planes Being Improved

Another concern established in Queens for a period of years is doing important experimental work, especially on the improvement of the curvature of the planes.

Motometers—Mahogany—Enameling and Japaning Plants

Besides the factories producing engines, planes, and propellers, there are allied industries which are of distinct advantages to the above-mentioned manufacturers. Four large mahogany importers and manufacturers are established here who can supply this necessary wood for the manufacture of propellers. Another company manufactures the aviaphone, which makes conversation possible between the pilot and the passenger, permitting the direction of the pilot for scouting and is especially useful in making maps and photographs because both hands are free to work.

The home of the distance type moto-meters for aeroplanes is in the Borough of Queens.

Reputed to be the largest ovens in New York State used for the enameling and japaning of aeroplane bodies and parts, is established in this section of New York City. It might be mentioned in passing also that anti-air craft guns are being made here.

Aeroplane and Automobile Industry Closely Allied

The aeroplane industry both in Europe and the United States has grown so suddenly and the need for a certain type of workmen has come into demand within so short a time that where no new factories have actually been built the tendency has been to use the automobile industries in the country for this highly specialized work.

This accounts no doubt for the existence in the Borough of Queens today of so many aeroplane industries and the operation by some of its autoombile factories in the work.

It should be kept in mind that the Borough of Queens has come to be practically the automobile center of the East, where 42 plants are engaged in the manufacture and assembling of automobiles, automobile parts and accessories with products for the year 1916 value at $37,448,000 and employing nearly 9,000 workers.

These manufacturers have built their plants here for very definite economic reasons. The same reasons apply to the production of aeroplanes.

Comparative cheapness in production, the relation of the Port of New York for export advantage, the coastwise shipping facilities, and the great rail transportation systems, give Queens Borough a unique position as a manufacturing and distributing center. It draws its labor from all parts of the enormous labor market in the largest city in the world, made quickly available by a network of rapid transit lines at a five-cent fare.

Many manufacturers have deterred from moving to New York City because of what they considered an excessive cost of factory space. This is an erroneous impression so far as Queens Borough is concerned, for in this section of New York, land is far less costly than in the older, built-up sections of the city, and still Queens Borough has all the advantages that any other part of New York City possesses. It is rapidly becoming the industrial center of New York and is today a borough of over a thousand factories.

Outstanding Advantage for Aeroplane Production

The outstanding advantages of Queens Borough for the production of aeroplanes are its location at the Port of New York, an inestimable advantage for shipment abroad, its enormous skilled labor supply, proximity to raw materials and semi-finished parts, accessibility to flying grounds on the vast stretches of Long Island.

All of these economic advantages compare favorably with any other section of the United States, but overshadowing every other advantage elsewhere is the location of Queens Borough at the port of exit of steamships to Europe. Shipment to the coast of a finished aeroplane is a difficult and expensive undertaking. Satisfactory production is possible only near a port of shipment.

Queens Borough is becoming the automobile and accessory center of the east. The production of the automobile and the aeroplane is so closely allied that they are practically inseparable.

CHATTANOOGA—A CITY OF DIVERSIFIED MANUFACTURING INTERESTS

By CHARLES W. HOWARD

Director of the Chattanooga Industrial Board

CHATTANOOGA is a city of diversified manufacturing interests,—321 manufacturers, producing 1,138 different articles, certainly give it a rather wide range. Proximity to the raw material, splendid distributing facilities has made it possible for Chattanooga in 20 years to take a front rank position with the leading manufacturing cities of the country.

Lumber, iron, coal, cotton, bauxite, barytes, limestone, and potters' clays, can all be assembled in Chattanooga on from a switching carload rate, to 50 cents per ton. With labor condi-

FOREIGN NEWS

FRANCE

Reporting operations on the western front, the French official announcement for March 28th says:

"On March 23 one of our groups of escadrilles carried out 125 patrols and 120 reconnoitering missions in the region of St. Quentin, Ham, La Fere and Noyon. More than 50,000 kilos of projectiles were dropped from March 22 to 26 on convoys, trains and enemy troop concentrations, which suffered heavy losses.

"Descending at times to within about sixty feet above the earth, our pilots attacked with machine guns enemy contingents, firing thousands of cartridges. Forty-two German aeroplanes and six captive balloons were brought down."

The official announcement of March 30th reports intensive aerial activity, as follows:

"On Wednesday and Thursday French aviators, notwithstanding the bad weather, continued their attacks against the German machines. Flying in groups the French airmen attacked the Germans with bombs and machine guns on the battle line and in the concentration zones. Several French machines made as many as three of these expeditions on the same day.

"Seventeen thousand kilograms (more than eighteen tons) of projectiles were thrown down in the regions of Guiscard and Ham. French pursuit squadrons in the course of numerous combats brought down thirteen German aeroplanes, of which seven were destroyed and six were damaged badly. Furthermore, two captive balloons were set on fire."

"Notwithstanding the unfavorable atmospheric conditions allied aviators carried out numerous bombardments along the whole front. An enemy machine was brought down in the region of the Struma," says the announcement of March 24th on the operations of the Balkan front.

GERMANY

Aerial operations in the great offensive which Germany has undertaken have assumed colossal proportions. The announcement of March 26th says:

"Since the beginning of the battle ninety-three enemy aeroplanes and six captive balloons have been brought down. Cavalry Captain Baron von Richthofen has achieved his sixty-seventh and sixty-eighth aerial victories; Lieutenant Bongartz, his thirty-second; First Lieutenant Loerzer, his twenty-fourth; Corporal Baumer, his twenty-third; Lieutenant Kroll, his twenty-second, and Lieutenant Thuy his twentieth."

Captain Baron von Richthofen, the German "ace of aces" is credited with two victories on March 27th:

"Captain Baron von Richthofen has achieved his sixty-ninth and seventieth aerial victories."

The official announcement of March 28th credits Captain Richthofen with further successes:

"Captain Baron von Richthofen has achieved his seventy-first and seventy-second aerial victories."

Captain Baron von Richthofen again is the only reference made to aerial activity, in the announcement of March 29th:

"Cavalry Captain Baron von Richthofen obtained his seventy-fourth aerial victory."

The announcement of March 30th says:

"Lieutenant Gongartz brought down his thirty-second and thirty-third opponents and Lieutenant Udet his twenty-second."

GREAT BRITAIN

Despite the gigantic effort of Germany to break down the British infantry, bombing attacks are continued by the British according to the announcement of March 25th:

"During the night one of the enemy's large bombing machines landed behind our lines. Following a successful daylight raid on Mannheim, other objectives in Germany were attacked during the night.

"Half a ton of bombs were dropped on the railway stations at Cologne, where a fire was started. Over a ton of bombs were distributted between the Luxemburg railway station, where a fire broke out, and Courcelles railway station, east of Metz. Two tons of bombs were dropped on the Metz railway station."

An official statement of the aerial operations March 26th says:

"On Monday our aeroplanes were employed almost entirely in bombing the enemy's troops and transports massed in the areas behind the battlefront and in attacking them with machine gunfire from low heights. Twenty-two tons of bombs were dropped in this work and over 100,000 rounds were fired from the machine guns.

"All our pilots reported that the ground targets offered by the enemy surpassed description. They were able to drop their bombs with accuracy and to fire with effect right into the center of infantry battalions in close formation and into columns of cavalry and transport.

"A certain amount of fighting in the air took place, but it was less intense than on the previous day. Thirteen hostile aeroplanes were brought down and ten were driven down out of control. The majority of our casualties were caused by the low-flying machines by fire from the ground.

"During the night our night-flying aeroplanes continued to bomb and attack with machine gun fire the enemy's troops in his forward areas and transport on the roads leading to the front."

Increasing work by the contact patrol of the British air service is reported in the announcement of March 27th as follows:

"Great concentrations of our aeroplanes were carried out today over points threatened by the enemy, and masses of our machines attacked with machine gun fire and bombs the enemy's infantry and cavalry.

"Thirty tons of bombs were dropped by us and hundreds of thousands of rounds of ammunition were fired into the enemy. While this fighting was maintained throughout the day, our infantry aeroplanes kept watch along the front and reported changes in the situation as they occurred.

"Twenty hostile machines were brought down in air fighting and two others were shot down by anti-aircraft guns. Twelve of ours are missing.

"During the night our night flying squadrons kept up a continuous attack on the enemy's troops in Bapaume, Cambrai and Peronne. Seventy-five thousand rounds were fired by them. Twenty-four tons of bombs were dropped on important centers of the battle front. In addition, four tons of bombs were dropped on the Valenciennes Railway station, through which the enemy's troop trains were passing on the way to the front."

British aviators took a heavy toll of lives as a result of their machine gun fire, according to the announcement of March 28th, which follows:

"Low flying was again carried out Wednesday by large bodies of our aeroplanes, while our infantry machines continued their work of reporting the positions on our battle line.

"More than thirty tons of bombs were dropped and a quarter of a million rounds of ammunition were fired from a height that insured accuracy on different targets.

"Severe casualties are known to have been inflicted on the enemy, and the bringing up of his troops and ammunition was delayed.

"Twenty-four German machines were brought down in the air fighting and seven were driven out of control. Two hostile observation balloons also were destroyed. Nineteen of our machines at present are missing.

"A proportion of these are believed to have landed on our side of the line. A very heavy fire directed against our machines from the ground accounted for the greater portion of our casualties.

"During the night the bombing of Bapaume, Bray and Peronne continued with the utmost vigor. Over a thousand bombs were dropped and thousands of rounds of ammunition were fired at good targets, which were plentiful and easy to see in the moonlight. Our pilots saw their bombs bursting in the middle of columns of troops, transports and encampments.

"Four of our aeroplanes are missing.

"On Wednesday the Sablons station at Metz was bombed, over ten tons of bombs being dropped. Explosions were seen on sidings and along the railway. Today our machines carried out a successful raid on the station at Luxemburg. Twenty-one heavy bombs were dropped and several were seen to burst on their objectives."

Sixteen German aeroplanes were put out of action on March 30th by the British, it is announced officially. The statement follows:

"A majority of our attacks were made on enemy groups on the battle front Thursday south of the Somme, where large concentrations of the enemy were constantly reported. The work continued until dark, in spite of rainstorms and low clouds. Twenty-six tons of bombs were dropped and nearly 250,000 rounds were fired upon different targets.

"There was not much fighting, considering the number of British machines in the air, but on the battle front the fire from the ground became very heavy. Nine German machines were brought down, five others were disabled and two others were shot down by fire from the ground. Twelve of our machines are missing."

Another British report on aviation issued March 30th says:

"A great deal of fighting took place (Friday), the ennemy's low flying machines being particularly active in this area. Nine hostile aeroplanes were shot down and two were driven down out of control. Two of ours are missing.

"During the night more than twelve tons of bombs were dropped on Bapaume and roads in the vicinity and also on roads and villages east of Arras. Direct hits were obtained on ammunition dumps and transport and railway lines. One of our machines is not yet located."

The British official announcement for March 31st reports aerial activity as follows:

"After noon Saturday the weather completely broke, but our airmen in spite of the driving rain continued to take part in the battle south of the Somme. There was heavy air fighting between our enemy and low flying machines. Twelve hostile aeroplanes were brought down and three were disabled. One hostile balloon was destroyed and two other German aeroplanes were shot down by our anti-aircraft guns. Five of our machines are missing."

Bruges was bombed by naval aeroplanes, says the announcement of March 25th, which follows:

"Three bombing raids were carried out on the Bruges dock, and many direct hits were obtained. Bombs were seen to burst close to destroyers. Several torpedo boats, a destroyer, and an armed trawler were attacked. One of our aeroplanes was forced to land in the sea. The pilot was picked up by a French destroyer. All the other machines returned safely."

ITALY

There has been remarkable aerial activity over the lines on the Italian front, the War Office announced March 25th. Eight enemy machines were brought down. There has been a lively artillery battle at various places between Lake Garda and the Brenta.

Italian aeroplanes bombed railway lines in the Lagarina valley and the aviation grounds on the Livenza.

The official announcement of March 26th reports the following aerial operations:

"Five enemy aeroplanes were brought down by our aviators at Val Dobbiateri, Moriago, San Pietro and Biadene. Another 'plane was brought down by the French aviators at Montebelluna."

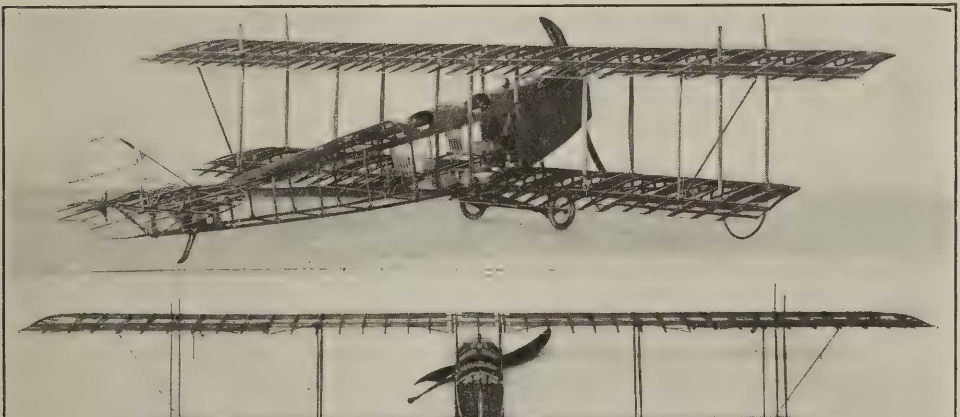
Scale Models of the Halberstadt and Wright Flying Boat

THESE two scale models were built by Mr. Jacob Dinnell, of Kent, Connecticut, and he sends us the following description of them:

The Halberstadt Chase plane has a wing spread of 30 inches and an overall length of 25 inches. It is an exact model of the famous Halberstadt D II which for a long time was the best type of German fighting machine. The fuselage is built up of 5/32 inch square basswood and is covered with rice paper and a heavy coat of varnish. The cowlings are of wooden frames covered with paper except for the engine hood which is of sheet aluminum. The motive power is furnished by 40 feet of 1/16 inch square rubber, driving direct onto a 9 inch propeller. The tail assemblage consists of a pair of elevators with a surface of 16 square inches and a vertical rudder with a surface 4 square inches, none of the Halberstadts having any vertical or horizontal stabilizing fins. The running gear is of 5/32 inch round reed mounting a pair of 2 inch rubber tired wheels. The 6 inch axle is held onto the struts by elastic bands which serve as shock absorbers. The main wing frames consist of two ⅛ x 3/16 inch beams with double ribs at intervals of 3 inches. These ribs are of 1/16 x ⅛ inch white holly and have a chord of 4½ inches. The ailerons are 4 inches long by 1½ inches wide and are counterbalanced in the same way as the rudder and elevators. The wings are covered on both sides with the same material as the body. The gap is 4 inches and the span of the lower wing is 3 inches less than that of the upper. There are six pairs of interplane struts, each of ⅛ inch round wood. The complete model weighs 10 ounces and for this reason it is not a distance flier but it rises from the ground and flies very well for a short distance.

The Wright Flying Boat has a spread of 3 feet and an overall length of 31 inches. The sides of its hull are of 1/16 inch board while the top and bottom are covered with two layers of varnished rice paper. The step is ½ inch high and from this forward the hull is V bottom. The power is furnished by 60 feet of 1/16 inch square rubber divided into four skeins. Two sprocket gears are mounted in the center of the hull and one skein runs from each end of both gears. The power is transmitted from there to the propeller shafts by fine brass chains. Each shaft mounts a 10-inch Wright type propeller. By using this method it not only allows you to have the propellers in the center of the machine but it does away with all bearing friction, as the pull is equal at both ends of the gears. The tail assemblage consists of a pair of horizontal fins with the elevators attached to their trailing edge. It has an area of 90 square inches and is raised 1 inch from the deck. The vertical fin and rudder stand 11 inches high and have an area of 20 square inches. The main wing frames are of ⅛ x ¼ inch wood with double ribs 3 inches apart. The aileron frames are of aluminum wire and the whole is covered with rice paper and varnished. The lower wing is four inches shorter than the upper and both chord and gap are 6 inches. There are four pairs of streamline struts and two pairs a little heavier, which hold the propeller shafts. The balancing pontoons are made in the same manner as the hull, the sides being of $\frac{1}{16}$ inch wood and the top and bottom of paper. They are 6 inches long and 2½ inches high at the stern and are held by aluminum wire struts. A full set of controls like those in use in the government training machines is installed in the cockpit just forward of the main planes. The tail and rudder are connected by threads and the ailerons by flexible wire working around ¼ inch pulleys.

Mr. Dinnell is now building an Albatross D-III and if it is successful will give us a description of it. The photographs of this model will appear in a later issue.



Three views of the unusually accurate scale model of a Canadian Curtiss J N 4 B aeroplane. The details are correct in all dimensions, being made from the actual blueprints of the Canadian Aeroplanes, Ltd., Toronto. Photos by courtesy of Mr. Ericson, in charge of the Canadian factory.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

The Fly-by-the-Light-o-the-Moon Co.

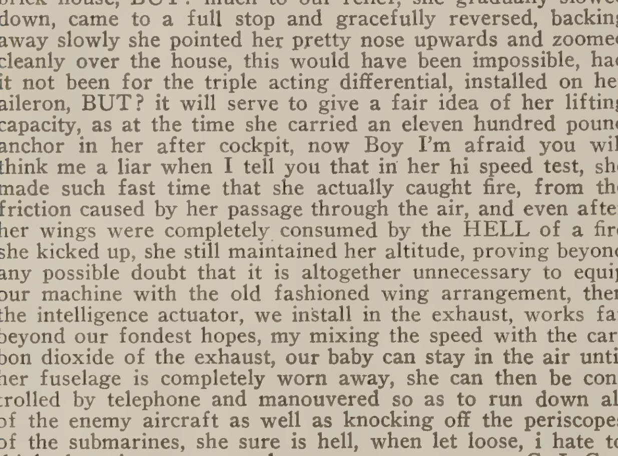
Gentlemen:—Our Fly like Hell, model 00 is a bear, it is really surprising, the stunts she capers through, say old scout, the first time i took her out i sure was astounded, as i opened her up, just a little, she humped her tail up under the landing gear, bucked twice and was off, of course she had been fitted with double acting longeron control which made her, to a certain degree automatic in her movements, nevertheless we were a trifle uneasy when we saw her heading straight for a brick house, BUT? much to our relief, she gradually slowed down, came to a full stop and gracefully reversed, backing away slowly she pointed her pretty nose upwards and zoomed cleanly over the house, this would have been impossible, had it not been for the triple acting differential, installed on her aileron, BUT? it will serve to give a fair idea of her lifting capacity, as at the time she carried an eleven hundred pound anchor in her after cockpit, now Boy I'm afraid you will think me a liar when I tell you that in her hi speed test, she made such fast time that she actually caught fire, from the friction caused by her passage through the air, and even after her wings were completely consumed by the HELL of a fire she kicked up, she still maintained her altitude, proving beyond any possible doubt that it is altogether unnecessary to equip our machine with the old fashioned wing arrangement, then the intelligence actuator, we install in the exhaust, works far beyond our fondest hopes, my mixing the speed with the carbon dioxide of the exhaust, our baby can stay in the air until her fuselage is completely worn away, she can then be controlled by telephone and manouvered so as to run down all of the enemy aircraft as well as knocking off the periscopes of the submarines, she sure is hell, when let loose, i hate to think about it, seems unreal.

G. J. C.

A Four Masted Cruiser

A description of our wonderful four masted atmospheric cruiser (The WILD PEGASSUS), seen from below it resembles four zeppelins tied together, its cargo capacity rivals that of seven ocean liners, it has the hertofore unattainable speed of 811¼ miles PER? & then some, her vertical longerons make her somewhat difficult to handle in a low breeze, otherwise she is as tractable as the ordinary tank in the air, it is a pretty sight to see her stall and zoom sideways, while her upside down performance is a marvel of grace, her delicate construction accounts for the installation of the 2700 h.p. steering gear on her hurricane deck. By the GERMANS she has been christened the YANKEE SNATCHER as she has been trained to hover over the battlefields and snatch HOWITZERS from the enemy, dropping them on the boarding-house of the KAISER, thereby causing much annoyance and loss of sleep to the bologna sausage tribe, her ocean work is also remarkable, she can without any apparent effort, by the use of her powerful magnet attached to her center-board, readilly lift the heaviest submarine from the ocean and unaided bring it to the base of operations, we are at present piling up all the submarines at the mouth of the kiel canal, causing its waters to back up and slowly but surely drowning out the enemy.

G. J. C.



THE INESTIMABLE SCOUT

Aviator (who has landed badly):—"Thank you, sonny, I'm all right; but you might see if that cow needs any attention, and then I want you to take my card to the Rector and say I'm awfully sorry about the spire. After that you will please send off this wire, and ask the local bicycle plumber to come here—and above all, don't forget to bring some cigarettes! I'll stay and beat off the souvenir hunters."—Courtesy Flying London.

The Diary of a French Building

1917	
Sept. 7 (3 p. m.)	Americans arrive.
Sept. 7 (3:10 p. m.)	Suggestions made to Buvette proprietor that he build an addition to his Buvette.
Sept. 29	Suggestion sinks in.
Oct. 14	Still sinking.
Oct. 23	The momentous decision.
Nov. 4 (8 p. m.)	Consults architect.
Nov. 4 (9:15 p. m.)	Plans completed.
Nov. 12	The first brick.
Nov. 14	The second brick.
Nov. 16	The third brick.
Nov. 17 to Dec. 1	Rest! Beaucoup de travail.
December (entire month)	Fate in the balance,—to be or not to be...
1918	
Jan. 4	The walls and roof meet.
Jan. 18	The iron gratings arrive.
Feb. 11	Work begun on the vaults.
Feb. 12	Work stopped to watch Sergt. Enowitz do a "Right by Fours."
April 15	Hurrah! Hurrah! The door knobs have arrived.
May 8	The door knobs don't fit.
June 11	The business of interior decorating.
June 11 (8 minutes later)	It's finished! The Building? No, the interior decoration!
June 15	It is suggested to the Frenchman that the building might have a floor.
June 18	"Yes, that's right, we ought to have a floor."
August 20	The grand opening! Loud cheers. Our first anniversary.
Later	Postponed indefinitely. They forgot the lighting.
1919	
Jan. 1	It's finished! It's finished!

(Continued on page 224)

(*Continued from page* 217)

tions, always favorable to manufacturing, electric power, rates not in excess of those at any other point, gives to the producer of any manufactured article from the raw materials named an advantage that is so apparent to the investigator that little remains except to secure a suitable location for his plant, after he has made a close investigation. It is these conditions that has enabled Chattanooga to double her population in less than 20 years, and to more than double the capital invested in manufacturing enterprises in 10 years. With a selling value on the manufactured product of approximately one hundred million dollars per annum.

The AERIAL AGE is catering to a clientele that did not exist 10 years ago, and yet in one decade, has developed from a fad to a national necessity. No manufactured article has had such a record of growth and it takes no vision to see that even with war needs on, the surface is not being comfortably skimmed. In a very few years, we will all smile over Post Master Burleson's conservative order for carrying mail between Washington and New York, by aeroplane service, but it is by such steps that ordinary business grows.

No better location for the production of aeroplanes could be found than Chattanooga. We have in the city 11 well-established wood-working plants, employing over 1,800 skilled wood workmen, with modern dryhouse capacity of over 250,000′ per day, with a finishing capacity of 230,000′ per day, and with shop floor space of 620,000 sq. ft. Pacific Coast spruce can be shipped to Chattanooga, thoroughly dried, put into proper shape, and be reshipped at a saving over the carrying cost of unworked spruce from the Pacific Coast to Eastern aeroplane producing points. Mahogany reaching any one of the five southern ports can be handled practically in the same way, naturally we have speculated as to just why these conditions should not be taken advantage of. The work of assembling these planes in Chattanooga would be less than at any of the present producing points, the one item of crating them will be 50% to 75% less. Dayton, Ohio; Pensacola, Fla.; Memphis, Tenn., are but 18 freight hours out of Chattanooga,—Norfolk, Va., not over 30,—San Antonio, Texas, not over 4 days. We have in addition to the wood-working establishments 25 to 30 foundaries running on grey iron, one steel castings foundry, one malleable iron, and one brass foundry. We also have a large stamping and enameling plant, so that many of the items that would make up an aeroplane could be very little, if any additional cost, made right here in Chattanooga.

Some day when we are manufacturing parcel post machines the astute manufacturer will discover that Chattanooga is the proper location for his business.

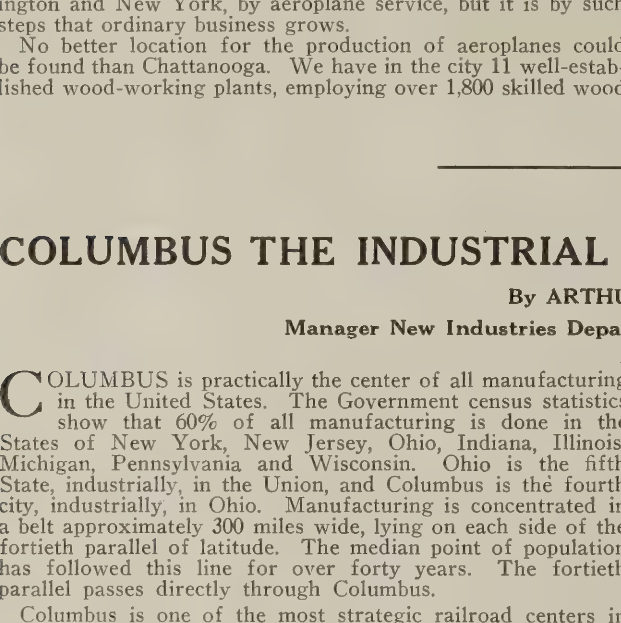
COLUMBUS THE INDUSTRIAL CENTER OF THE UNITED STATES

By ARTHUR B. LEONARD

Manager New Industries Department, Columbus Chamber of Commerce

COLUMBUS is practically the center of all manufacturing in the United States. The Government census statistics show that 60% of all manufacturing is done in the States of New York, New Jersey, Ohio, Indiana, Illinois, Michigan, Pennsylvania and Wisconsin. Ohio is the fifth State, industrially, in the Union, and Columbus is the fourth city, industrially, in Ohio. Manufacturing is concentrated in a belt approximately 300 miles wide, lying on each side of the fortieth parallel of latitude. The median point of population has followed this line for over forty years. The fortieth parallel passes directly through Columbus.

Columbus is one of the most strategic railroad centers in the United States, because of its geographic location and commercial importance. The Government of the United States has already recognized this fact by locating here its largest army recruiting depot and training school. One of the largest aviation ground schools in the country has been established here in connection with the Ohio State University. The Pennsylvania Railroad Co. has located here one of its largest repair shops, and has just let contracts that will materially increase the capacity of these shops. The State of Ohio has located practically all of its institutions here, including the State Capitol and the University; and Henry Ford, the great automobile manufacturer, has established in Columbus one of his largest assembling plants. In other words, the greatest Government, the greatest railroad company, the greatest State, and the greatest manufacturer have already recognized the geographical and railroad advantage of Columbus. Columbus has sixteen railroad divisions, as follows:



MAP SHOWING TERRITORY WITHIN A FIVE HUNDRED MILE RADIUS

Pennsylvania Lines West—Pittsburgh Division, Indianapolis Division, Little Miami Division, Toledo Divsion, Akron Division.

Baltimore & Ohio—Newark Division, B. & O. Southwestern Division.

Hocking Valley—Toledo Division, Hocking Division.

Big Four—Cleveland Division, Cincinnati Division.

Toledo & Ohio Central—Western Division, Corning Division, Eastern Division, St. Marys Division.

Norfolk & Western.

There are eleven electric railways operating out of Columbus in all directions.

For power purposes Columbus can offer electricity, steam or gas. Electric current in Columbus is produced and sold as low as three-fourths of a cent per kilowatt hour. Even the famous water power plants of Niagara Falls do not sell it any cheaper. Natural gas for industrial purposes may be had in Columbus as low as 15c per cubic feet, the rate depending upon the mixmimum consumption. The gas supply for Columbus is assured for many years to come and is a great industrial asset. The proximity of Columbus to the coal fields of Ohio and West Virginia make Columbus one of the leading coal centers in the United States. Columbus gets the advantage of low prices on coal because of its advantageous location, midway between the fields of Ohio and those of West Virginia. Coal to the lakes passes through Columbus by the millions of tons. Even during the serious coal shortage of the past winter, Columbus suffered much less than other industrial centers because of this fact.

The labor supply in Columbus is ample. Intelligent and skilled workmen and an exceptionally good class of common labor is available. Columbus has never suffered a severe industrial strike and its amnufacturing establishments individually or as a whole are free from disturbances of this kind. In fact, one of the strongest arguments for Columbus, industrially, is its freedom from labor troubles; and best of all, Columbus labor is American labor.

Realty conditions in Columbus are such that Columbus manufacturers possess many advantages. Many of the industrial plants are located just outside the city limits where they

Maximum Production Made Possible Through Intensive Co-operation in A British Aero-Engine Factory

Were All Your Grinders, Drills, Lathes, etc., Working for Uncle Sam's Aircraft Program Last Month?

If they were not working every available hour it is your duty to make your capacity known to the aeronautic concerns that are under contract to the Government—that are helping Win the War in the Air for the Allies.

Ask our CONTRACT WORK DEPARTMENT how you can help.

New York City

Advertising Builds Up Good Will and Saves Taxes

enjoy the privileges and benefits of city utilities, while paying the much lower tax rate of the township. The tax rate in Columbus at present is $1.40 per $100.00 of assessed valuation, and industrial property is commonly assessed at about 60% of its actual value. Columbus is in the forefront of American cities in its public utilities, possessing one of the finest and largest water purification plants, a municipal lighting plant, sewage disposal plant, garbage disposal plant, all municipally owned and operated. At the same time the per capita debt of Columbus is much lower than that of the average American city of its size.

Living conditions in Columbus are exceptionally good. The 40th parallel of latitude passes directly through Columbus and is marked by a boulder in the campus of the Ohio State University. It has been recognized by the best authorities for many years that the best climate is to be found in close proximity to the 40th parallel. Columbus is a city of home owners. An unusually large percentage of wage earners own their homes. The residents of Columbus are largely American born and are intelligent and congenial. Beautiful streets, picturesque streams, large parks and playgrounds, fine state institutions and grounds, including the State Capitol, splendidly appointed clubs, are added attractions. Sixty large public school buildings and a number of private and parochial schools offer excellent facilities for education. The Ohio State University with its courses in business administration, all branches of engineering, medicine, agriculture, arts, and aeronautics, is one of the greatest institutions of its kind in the world.

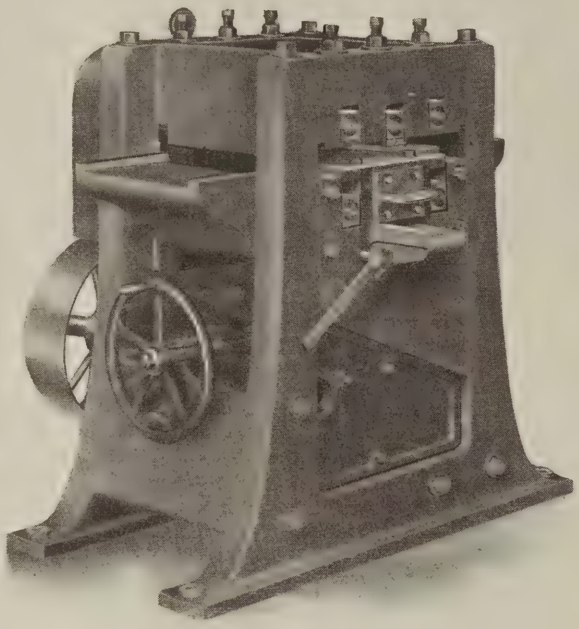
All the large manufacturing establishments in Columbus are cooperating with the United States Government in producing war material. There are several large companies now in Columbus that are making parts or accessories of aeroplanes. Among the products now being manufactured here for this purpose are gears, drop forgings, wheels, air pumps, oil pumps, water pumps, air relief valves, pump plugs, cam shaft housings, rocker arm coverings, bearing supports, various screw machine products and metal stamped goods. These products are now being shipped to Berkeley, Cal.; Buffalo, N. Y., and Dayton, Ohio. Columbus is one of the largest centers of die tool making in the United States, and large quantities of die tools for aeroplane factories are now being turned out in Columbus. One of the most up-to-date foundries for aluminum castings has just been established here to meet the demands of the aeroplane industry. Columbus for years was famous as the buggy center of the United States. These former buggy plants are available for making the bodies, propellers and other wood parts for aeroplanes. In other words, Columbus is a first-class location for an assembling plant. We have all the important requisites at hand.

The attitude of the community may have an important bearing on the proper location for such an industry. Columbus has already gained fame for the exceptional manner in which her citizens have responded to all the calls for service in the present war. Both of the Liberty Loans were very largely oversubscribed in Columbus; the Red Cross fund, the Army Y. M. C. A., and other war relief funds have likewise been responded to most generously here, much larger sums being given than were asked for. The most recent proof of willingness to do her part in the war, was shown by the remarkable success of the Community War Chest campaign. The plan of having a community fund to meet the constantly recurring needs of war relief work is one which Toronto, Canada, has used successfully. Columbus undertook to raise a fund of $3,000,000 for such a War Chest, and in a four days' campaign her 250,000 citizens pledged a quarter of a million more than had been asked for. This is about $13.00 for every man, woman and child in our community.

To sum up the advantages of Columbus: We have unexcelled railroad facilities with direct traffic line service to the chief Atlantic ports. Industrial conditions are exceptionally good in Columbus, whether considered from the standpoint of labor supply, accessibility of raw materials, realty conditions, or cost of power. Much of the preliminary work in aeroplane manufacture has already been gone through by Columbus manufacturers and workmen have been trained to the accuracy and skill which is necessary in this type of work. There is no industrial city in the United States in which living conditions are superior to those in Columbus. The housing code regulating the construction of residences and tenements is a model all over the country. Street car service with eight tickets for twenty-five cents makes it possible for the workman to live amid pleasant surroundings. Columbus is therefore an ideal city in which to do business; it is an ideal city in which to live; and, best of all, Columbus has a Chamber of Commerce composed of about 1,800 of the most active citizens of the community, anxious to promote its growth and prosperity.

Aeroplane Propeller Stock

Toothed at the rate of 100 feet per minute by running it through a



Whitney Scraping and Toothing Machine

WHITNEY

Toothing Machine

If you want to prepare your Propeller stock before gluing up by the quickest—easiest—safest and cheapest method, just put it through a Whitney Toothing Machine.

Many of the Aeroplane Manufacturers, as well as Propeller Makers, are using this machine.

It will pay you to investigate.

Aeroplanes Drop News to Belgians

Senator Henri La Fontain of Belgium, president of the executive committee in the United States of "Gifts for Belgian Soldiers," says that President Wilson's messages have greatly comforted the Belgians.

"There was great rejoicing last week in the occupied portion of Belgium. Allied aviators dropped in large quantities the complete text of President Wilson's speech, which was printed in small letters on cardboard sheets. At Liege many thousands were found, and our unfortunate compatriots, whose morale is always excellent, were greatly comforted.

"Many disputes arose between Belgians and Boche officers, who certainly did not always have the last word. There were many who remarked openly that the words of M. Clemenceau, Lloyd George and President Wilson had given them strength to wait two years or more if need be for the defeat of the Germans.

"Every one is anxious to have allied aviators keep them informed about present events, and nothing else could contribute more to help these Belgians living under German rule to endure District, in order to serve in the Aviation Section. He has made several speeches in Italy since his arrival there on duty.

Louis Seguin Dies in France

Louis Seguin, chairman of the board of the Gnome and Le Rhone Engine Co. and a pioneer in the development of aeroplane motors, died in Paris on March 7th. His grandfather was Marc Seguin, the French engineer who invented the water tube boiler. Louis Seguin organized the Gnome Engine Co. in 1895, which developed the Gnome and later the Le Rhone rotary aircraft engine. Both of these are being built in the United States for use on war aeroplanes.

Personal Paragraph

James E. Kepperly has been appointed general manager of the Curtiss Aeroplane & Motor Corporation of Buffalo, succeeding William A. Morgan. Mr. Kepperly has been associated with the Willys interests and is vice-president and counsel of the Willys-Overland, Inc. Mr. Kepperly has also been elected vice-president of the Curtiss Company, a member of the executive committee and a voting trustee.

New Aeroplane Flown to Washington

Robert Bounds of the Standard Aircraft Corporation of Dayton, Ohio, arrived in Washington, Friday afternoon, at three o'clock, having started from Dayton in the morning at 7 o'clock, negotiating the distance of 700 miles in a little more than eight hours. This establishes a new time record for a continuous non-stop flight across mountainous country.

The machine in which the flight was made is a new National biplane, armored, and driven by a Husitano engine, and can develop a maximum speed of 100 miles an hour. It has been tested thoroughly at Dayton, but has not been tried out by the government. It is announced that a series of tests is to be made here in an effort to have the plane adopted by the government as a battle plane.

Aviators Solve Technical Problems by Daily Study in Battle Conditions

It is clear from the reminiscences of Captain Guynemer, which are now being published, that the construction of an aeroplane is a matter of daily, even hourly, preoccupation. The aviator, that is if he is in the class of Captain Guynemer and Captain Duchenne, is a technician, working industriously with the manufacturer in the shop. Perhaps the yachtsman who watches the building of his yacht, and even has something to do with its design, is the closest parallel. The most successful aviator has at his command all the devices of the shops, all those magnificent tricks of the trade which make his achievements one of the marvels of the age. The public might miss this vital point. The test of the aviator is his technique. If he knows how to make a machine, and this is knowledge that can be taught, he can always capture the air.

The training and education of aviators is therefore an all important element of success. This training is an affair of science. The opinion of an English writer illustrates the point. He says: "The mastery of the world depends, it is clear, largely on a knowledge of science. Never was there a greater object lesson in regard to this than the present war. Perhaps the most conspicuous example is to be seen in the air. The war has forced men with feverish haste to learn its laws and to develop machinery for dealing with them. It is applied and technical science that is needed." Further experience has only confirmed what has been said as to the importance of gradual evolution in aeroplane construction.

Barlow Bomb Being Tested

Concentration of attention on the mysterious bombardment of Paris has revived interest in the Barlow aerial torpedo. It is said the soundness of the principle is conceded by experts of the army and navy.

Representative Hillson, of Connecticut, has taken a lively interest in the idea, and maintains that it should be elaborately experimented with at once. He is of the impression that the signal service is working on it, but as nearly as can be ascertained the service has as yet made no definite deal with L. P. Barlow, the inventor. It is said the signal service has "stalled" him for six months on these bombs. Now Congress is to be asked for an independent appropriation for an investigation of the merits of the aerial torpedo.

Message by Pigeon Saves Naval Aviator

Emery Stone, a naval aviator, who had been missing since March 5, has been picked up at sea by a patrol boat and was safe in an English hospital.

Engine trouble had forced him to alight on the ocean in his hydroaeroplane March 5, the aviator sending word of his plight to the American naval base by a carrier pigeon. A second message said Stone was picked up after floating four days. He is suffering from exposure.

STATEMENT OF THE OWNERSHIP, MANAGEMENT, CIRCULATION, ETC., required by the Act of Congress of August 24, 1912, of AERIAL AGE WEEKLY, published weekly at New York, N. Y., for April 1, 1918.

County of New York, }
State of New York, } *ss.*

Before me, a Notary Public in and for the State and county aforesaid, personally appeared G. Douglas Wardrop, who, having been duly sworn according to law, deposes and says that he is the Business Manager of the AERIAL AGE WEEKLY and that the following is, to the best of his knowledge and belief, a true statement of the ownership, management (and if a daily paper, the circulation), etc., of the aforesaid publication for the date shown in the above caption, required by the Act of August 24, 1912, embodied in section 443, Postal Laws and Regulations, printed on the reverse of this form, to wit:

1. That the names and addresses of the publisher, editor, managing editor, and business managers are:

Publisher, Aerial Age Co., Inc., 280 Madison avenue, City.
Editor, G. Douglas Wardrop, 280 Madison avenue, City.
Managing editor, G. Douglas Wardrop, 280 Madison avenue, City.
Business manager, G. Douglas Wardrop, 280 Madison avenue, City.
Assistant business manager, Geo. A. Cavanagh, 280 Madison avenue, City.

2. That the owners are: (Give names and addresses of individual owners, or, if a corporation, give its name and the names and addresses of stockholders owning or holding 1 per cent or more of the total amount of stock.)

Aerial Age Co., Inc., 280 Madison avenue, New York City.
Henry Woodhouse, 297 Madison avenue, New York City.
G. Douglas Wardrop, 280 Madison avenue, New York City.

3. That the known bondholders, mortgagees, and other security holders owning or holding 1 per cent or more of total amount of bonds, mortgages, or other securities are: (If there are none, so state.) None.

4. That the two paragraphs next above, giving the names of the owners, stockholders, and security holders, if any, contain not only the list of stockholders and security holders as they appear upon the books of the company but also, in cases where the stockholder or security holder appears upon the books of the company as trustee or in any other fiduciary relation, the name of the person or corporation for whom such trustee is acting, is given; also that the said two paragraphs contain statements embracing affiant's full knowledge and belief as to the circumstances and conditions under which stockholders and security holders who do not apppear upon the books of the company as trustees, hold stock and securities in a capacity other than that of a bona fide owner; and this affiant has no reason to believe that any other person, association, or corporation has any interest direct or indirect in the said stock, bonds, or other securities than as so stated by him.

5. That the average number of copies of each issue of this publication sold or distributed, through the mails or otherwise, to paid subscribers during the six months preceding the date shown above is: (This information is required from daily publications only.)

G. DOUGLAS WARDROP.
Editor, Business Manager.

Sworn to and subscribed before me this 23rd day of March, 1918.

DANIEL F. NUGENT.
(My commission expires March 30, 1919.)

LET US STOP DEALING WITH MINIMUMS

By ALAN R. HAWLEY, President, Aero Club of America

OUR aeronautic accomplishments in the first year of war consist mainly of things that we have learned (let us hope) through experience and mistakes.

Let us hope that we have learned the size of the task of defeating Germany and the fallacy of relying on minimum.

As we look back to this one year of experience we see that the air program was not equal to the task of whipping Germany through the air.

The greatest of our national sins in the past year has been over-reliance on minimums—minimum plans, based on minimum understanding of the military situation, further weakened by minimum appropriations. We have also had some minimum men, having minimum knowledge and experience, who did not anticipate, as one must do in war times, the possible necessity of quick expansion, as well as possible delays, due to transportation of materials, labor conditions, mistakes, etc.

The one national resolution that we ought to make on the first anniversary of our entrance in the war should be to eliminate minimums of all kinds and adopt maximums in programs, men, appropriations, manufacturing facilities, etc. Having adopted maximums, let us add to each so as to have a substantial margin of safety to insure success under any circumtances.

The Air Program of July, 1917, was the rock-bottom plan made when Italy was victorious and Russia was still fighting.

It was based on the assumption that the Allies had Germany practically beaten and only needed some assistance to complete the task.

This program did not take into consideration that it takes an average of two aeroplanes to give an aviator the one hundred hours of preliminary and advanced training needed to make him fit for the present-day highly specialized work of a military aviator. Nor did it take into consideration that it takes close to one hundred per cent. replacements per month in aeroplanes and motor to keep aviators equipped for fighting. Nor did it take into consideration that it takes forty per cent. replacements in aviators per month to keep up the fighting personnel of aero squadrons.

In making this program the fact was overlooked that if the plan was to keep five thousand American aviators at the front, it was necessary to train twenty-five thousand. Therefore there would be required fifty thousand preliminary and advanced training aeroplanes with which to train them speedily. The number of aeroplanes under construction today is not sufficient to even give the preliminary and advanced training to the number of aviators the United States must supply within the coming twelve months.

There was also overlooked the fact that to keep five thousand aviators equipped for action, there would be required a rock-bottom minimum average of two thousand aeroplanes of different types per month, or a total of twenty-four thousand machines of different types during the twelve months.

Having overlooked these very important considerations, the authorities could not undertake to supply all the aeroplanes needed out of the twenty-two thousand planned in the July, 1917, program, to be completed by July, 1918. The Italian and Russian reverses created imperative needs, and the authorities received cables requesting thousands of aeroplanes of diffrent types. Lacking the funds necessary to place additional orders, the authorities changed the orders of aeroplanes under construction which they placed, so as to meet the requests from France. As the requests from France and the suggestions from the different Allies were different types of machines, the authorities kept on changing the orders, so as to supply those machines for which there seemed to be the most pressing need. This led to the continual changes which caused the setbacks which have resulted in the aircraft program—which is still the same program made at the time when Italy was victorious and Russia was still fighting—being behind by several months.

Had the authorities been in a position to place additional orders whenever they received cables asking for a given number of machines of a given type, instead of having to change orders for machines under construction, today the original program would be nearly delivered and an additional program would be well under way.

Today we are making the same mistake that was made then. We are stopping the enlisting of aviators, and no steps have been taken to extend the program to meet the new conditions which have arisen, and which, unless they are met properly, may result in Allied reverses.

We have followed the aircraft program step by step and are familiar with the inside problems that have caused the delays. These causes are numerous, but the main ones are:

(1) Lack of concentrated responsibility, authority and control in the management of aerial matters.

(2) Lack of sufficient appropriations to extend the aircraft program to meet the military needs of the Allies.

(3) Lack of touch between the authorities dealing with the strategic side of the war and the authorities having charge of the supplying of aircraft and aviators needed to build American and Allied forces.

(4) The lack of a Government department having the authority and organization necessary to deal with all aircraft matters and prevent delays due to division of responsibility, bureaucratic jealousies and official squabbles over matters of departmental jurisdiction, duplication of efforts, etc. The present Aircraft Board is only an advisory board and has no power to act or to get the necessary organization to extend or carry out an extended aircraft program.

To correct the situation, two successive steps must be taken, as follows:

(1) The immediate appointment of an Assistant Secretary of War and an Assistant Secretary of the Navy to represent the Army and Navy, respectively, in the Aircraft Board. This is to solve the immediate problems while the second step is being taken.

(2) The creation of a Department of Aeronautics based on the British plan, which places the Air Services under a separate Department of Aeronautics, the head of which is independent of, although co-operating closely with, the War and Navy Departments.

The British Government went through every one of the troubles we have gone through in connection with our air service. The official reports of the investigation of the British

Air Service in 1916 shows that there were scandals and charges, counter-charges and confusion, just as we have in the United States today. After three years of trying different plans, the military and naval authorities and other branches of the British Government came to the conclusion that the only solution was a separate Department of Aeronautics, with an Air Minister at the head, whose functions are identical with the duties of the War Minister and the First Lord of the Admiralty.

A separate Department of Aeronautics is the only solution to all the problems of building the air forces needed to win the war.

We must see that many of the officials in charge of the aircraft program and the members of their staffs are able men who, if placed in a Department of Aeronautics and given the power necessary to act and to get together an efficient organization and the necessary funds, will quickly save the situation and enable the United States to do its share in the air this year.

It is well to add that an important consideration that led to the creation of the Air Ministry in Great Britain was the knowledge that Germany is planning extensive aerial mail, express and passenger transportation lines, to employ the output of her aircraft factories after the war. Germany's plans are extensive enough to employ tens of thousands of aircraft. This would give her a reserve air fleet large enough to blow England, France or Italy off the map overnight.

As was brought out in the House of Commons by Lord Montague, aircraft can be turned from vehicles of transportation to war machines by the simple process of substituting bombs as cargo. A nation that overlooks this fact may pay dearly for its oversight.

We all hope, of course, that some agreement may be reached between the nations which will guarantee against such a horror as the bombing of a nation out of existence overnight by another nation having tens of thousands of aeroplanes. But the present war has shown that hope does not save nations from the outrages of aggressors. As a matter of fact, Germany's first air raids of Great Britain were conducted by Zeppelins, which were employed for passenger carrying before the war. So while keeping our hearts in the right place, we must be ready to protect the Republic and the rights of humanity and the Cause of Civilization. To do this will require direct control and supervision of military and commercial air fleets, and this can only be done by a well organized Department of Aeronautics.

Let us emphasize again the necessity of making a national resolution to eliminate minimums of all kinds and adopt maximums in programs, men, appropriations, manufacturing facilities, etc. Having adopted maximums, let us add to each so as to have a substantial margin of safety to insure success under any circumstances.

BELMONT PARK IS LANDING FIELD FOR MAIL SERVICE

BELMONT PARK in New York, Potomac Park in Washington and Bustleton, north of Philadelphia, have been selected by the Postoffice Department for landing fields for the aerial mail service to be inaugurated between the three cities next month. The work of preparing the fields and erecting the hangars will be pushed as rapidly as possible, assuring the inauguration of the service at the latest by May 15, it was officially announced.

The tentative schedules announced by the Postoffice Department give New York the benefit of greatly improved mail service. An aeroplane leaving Washington at noon, as now planned, will reach New York in time to permit a late afternoon delivery throughout the city. To make this delivery by train letters now have to be mailed here before 9 A. M.

The Postoffice Department's official announcement of the new service says:

Work to Be Rushed

"The three landing fields for the aerial mail service have now been selected, and the work of preparing the fields and erecting the hangars will be pushed as rapidly as possible. The service will be in operation not later than May 15. The date of its inauguration may be advanced considerably.

"The three landing fields selected are Potomac Park, for Washington; Bustleton, North Philadelphia, for Philadelphia, and Belmont Park for New York.

"Difficulty was experienced in the selection of a landing site in New York, on account of the high rental asked for a suitable property. The Westchester Racing Association, in a spirit of patriotism, tendered Belmont Park to the Government for this purpose free of charge, and the offer was accepted.

"The hangars at Potomac Park are now in course of construction and the work at Bustleton and Belmont Park will be speedily begun. Extensive rolling and grading of the Philadelphia field is necessary, but the work will all be done during this month.

"Assuming that the aeroplanes leave New York for Washington at noon and leave Washington at the same hour for New York, rail connections for destinations beyond these cities and Philadelphia will be made which would otherwise be impossible.

Much Time Saved

"Besides the saving of much time in the delivery of letters addressed to New York, Philadelphia and Washington, there will be a large time saving through making these connections for earlier trains to the points beyond the terminals. An aeroplane leaving New York at 12 noon, arriving at Philadelphia at 1:30 and at Washington at 3:30, will connect with earlier trains than those conforming to the train schedules from New York for Camden, Atlantic City, N. J.; Paoli, Lancaster, Harrisburg and Chester, Penn.; Wilmington, Del.; Point Deposit, Md.; Cape May, Reading and Pottsville.

Mail arriving at Washington by airoplane at 3:30 would make connections with the Baltimore & Ohio train leaving Washington at 4 P. M. for Cumberland, Grafton, Pittsburgh, Cincinnati and St. Louis. It would also make connection with the Southern train leaving Washington at 4:15 P. M. for Charlottesville, Lynchburg, Danville, Va.; Greensboro, Salisbury and Charlotte, N. C.; Atlanta and Birmingham.

To Gain Eight Hours

"The time saved on these connections would amount to eight hours or more. In order to make these connections by rail it would be necessary for mail to be dispatched from New York at 8 A. M.

"On account of the more frequent train service and different schedules of trains going north the saving of time would not be as great to outlying stations for northbound mail.

"Letters dispatched by air route from Washington will at Philadelphia connect with earlier trains for Trenton, Manunka Chunk, N. J., and East Stroudsburg, Chester, Wilmington, Camden, Atlantic City, Cape May, Reading, Pottsville and Bethlehem.

"At New York earlier connections will be made for Bridgeport, New Haven, Springfield, Boston, Albany, Syracuse, Rochester, Buffalo, Cleveland, Toledo, Elkhart and Chicago.

"An aeroplane leaving Washington on this noon schedule would make the late afternoon city delivery over the entire City of New York. To make this delivery by train letters now have to be mailed before 9 A.M."

"Belmont Park is the ideal New York terminal of the Washington-New York aeroplane mail line," said Messrs. Alan R. Hawley, President of the Aero Club of America and Henry Woodhouse, a member of the Board of Governors of the Club, "and the postal authorities are to be complimented on their wise selection."

"The Aero Club authorities selected Belmont Park in 1910 for the first international aviation meet and found it ideal in every way. By offering the use of Belmont Park to the postal authorities, Major August Belmont, who is an old member of the Aero Club of America, again demonstrates his practical patriotism. This is only one of the many contributions which he has made to advance the cause of national defense in aeronautics.

"The aerial mail carrying project is much closer to the cause of national defense than many people realize. Had the postal authorities been permitted to establish aerial mail lines several years ago, it would have given great impetus to the development of large mail carrying aeroplanes and high-powered motors and we would today have extensive sources of supplies of these machines with which to strike Germany through the air.

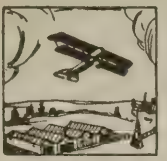
"There would also have been trained hundreds of aviators in cross-country and night flying, which would have given a reserve of trained aviators to use against Germany upon our entry into the war.

"It is highly gratifying that the War Department will co-operate to the fullest extent with the Post Office in rushing these aerial mail lines, using military aviators to pilot the postal aeroplanes, thereby giving the aviators extensive cross-country flying.

"It is an efficient combination, which will develop trained aviators, and at the same time enable New York, Philadelphia, Washington, Camden, Atlantic City, Harrisburg, Wilmington, Boston, Albany, Buffalo, and other cities to get their mail many hours sooner.

"The fact that this one air line increases the efficiency in the delivery of mail in so many cities gives an idea of the efficiency of the aerial mail service and insures establishing other aerial mail lines throughout the United States in the near future.

"There are thousands of aviators who still have to receive their advanced training, and whose training can be combined with the delivery of mail in different parts of the United States."



THE NEWS OF THE WEEK

New Department of Aeronautics is Probable Now

Washington. — Sentiment in Congress is growing fast for a "Department of Aeronautics."

In fact it is more than likely that a bill soon will be introduced providing for such a department with a secretary at its head who will have the same standing as a cabinet officer and authority as both the Secretary of War and the Secretary of the Navy.

Under the present system the Aircraft Production Board may only make recommendations to either the War or Navy Departments which may or may not be carried out in the Signal Corps of the army or the Naval Aviation Service.

Under the proposed department scheme the men now in these two branches of the service would be transferred to the "Flying Corps," which would be a consolidation of both.

When Murray Hulbert, Dock Commissioner of New York, was a member of the House he introduced a bill for the creation of a Department of Aeronautics, but it met with the disapproval of the Administration and was lost. However, it was due to that bill to a large extent that the present Aircraft Production Board was created.

President Names New Aids to Baker

Washington.—President Wilson sent to the Senate April 8 the nominations of Edward R. Stettinius and Frederick F. Keppel, both of New York, to be Assistant Secretaries of War. They will fill two new offices created to carry out plans for placing the War Department on a better basis to carry on the conduct of the war. Both nominations had been forecast.

Mr. Stettinius was a partner in J. P. Morgan & Co., and as such had charge of the purchase of war supplies for the Allies in the United States before the United States entered the war. He is now Surveyor General of Purchases under the Director of Purchases in the War Department. Senators who favored the creation of a War Cabinet of three members cited Mr. Stettinius as the kind of man needed for that proposed body. Dr. Keppel is Dean of the College of Columbia University, New York. He has been a voluntary assistant to the Secretary of War and one of Secretary Baker's most intimate official associates.

Industrial Service Section of Signal Corps Is Created

The War Department authorized the following statement:

The appointment of Charles P. Neill, of Washington, D. C., manager of the Bureau of Information, Southeastern Railways, and former United States Commissioner of Labor, as chief of the Industrial Service Section of the Signal Corps, and of W. Jett Lauck, of Washington, D. C., editor of the *Labor Gazette,* and former mining expert and consulting statistician of the United Sattes Commission on Industrial Relations, as his assistant, completes the War Department's program of creating in each important procuring bureau an organization for the development and maintenance of satisfactory relations between employers and employees engaged in production for the Army.

The sections organized are:

Industrial Service Section of Ordnance Bureau, in charge of Herman Schneider; location, Sixth and B Streets; telephone, Main 2570, branch 449.

Industrial Service Section of Quartermaster Department, in charge of E. M. Hopkins; location, 1800 Virginia Avenue; telephone, Main 2570, branch 2396.

Industrial Service Section of Signal Corps, in charge of Charles P. Neill; location, 161 Woodward Building; telephone, Main 3670.

Industrial Service Section of Construction Division, in charge of Col. J. H. Alexander; location, Seventh and B Streets; telephone, Main 2570.

The work of these sections is being carried on in close co-operation with the Department of Labor and is being co-ordinated through the office of the Secretary of War with the Labor Administration.

Approves St. Louis-Chicago Aerial Route

Postmaster Selph of St. Louis announced that the Postoffice Department had approved his idea for aerial mail service between St. Louis and Chicago, provided suitable landing fields can be found in the two cities. Aeroplanes would leave Chicago and St. Louis simultaneously.

Colonel Montgomery Made Member of General Staff

By direction of the President, Colonel Robert L. Montgomery is detailed as a member of the General Staff Corps for the period of the present emergency. Colonel Montgomery, while discharging this duty, will continue as a member of the Aircraft Board.

Evan J. David Lectures to Baltimore Engineers

Evan J. David, business manager of "Flying" monthly, addressed the Engineers' Club of Baltimore on April 4. Mr. David touched on all phases of aeronautics, beginning with the construction of the aeroplane in the factory, and ending with its destruction over the field of battle.

Wright Buys Indiana Plant

The Wright Aeroplane Company of Dayton, Ohio, has purchased the plant of the Union City Body Works of Winchester, Indiana. This plant will be used for the manufacture of aeroplane parts. Two hundred and fifty men will be employed here.

Standard Aeroplane Gets to Capital in Record Time

A new National biplane flew from Dayton, Ohio, to Washington, a distance of over 700 miles over mountainous country, in little more than eight hours. The aeroplane was constructed by the Standard Aircraft Corporation, equipped with a Hispano-Suiza engine and piloted by R. Bounds.

Navy Uses Liberty Engine

According to information from Washington, the Navy Department has more than 80 aeroplanes equipped with Liberty engines. A Liberty equipped plane on March 28, attained an altitude of 21,500 feet. Announcement was also made, according to "Automotive Industries," that General Pershing has well over 100 combat aeroplanes in his organization. It is not stated, however, that they are of American construction.

At the Aviation Schools

Changing a spark plug in mid-air, while flying near the Curtiss School at Miami, is the feat performed by Joseph Bennett and Paul Bickey. The plug was changed at an altitude of 8,000 feet and flight resumed in less than four minutes.

Richard Mansfield, son of the late Richard Mansfield, who enlisted in the Aviation Section of the Signal Corps in New London, Conn., on February 1 last, died of spinal meningitis at the aviation training camp, San Antonio, Texas. His mother, who was Beatrice Cameron, an actress of distinction, has been so informed.

With Washington as their final destination, Brigadier-General W. L. Kenley, chief of the United States Army air forces, and Major C. K. Rhinehardt, his pilot, prepared to leave Kansas City for Omaha, where the General will inspect the army balloon training camp. The General is making a round of all army aviation camps by aeroplane.

"Simply travelling that way to save time," he said when he and his pilot alighted here after flying from Fort Sill, Oklahoma. They had flown there the day before from San Antonio, Texas.

Rodman Law, balloonist and aeronaut, attached to an aero squadron at Kelly Field, jumped from an aeroplane at a height of 2,500 feet, and with the aid of a parachute, landed safely. He was taken up in an aeroplane by Edward Stinson, an instructor at Kelly Field.

Law is making a series of experiments to demonstrate the feasibility of jumping from an aeroplane. He is a brother of Miss Ruth Law, and Edward Stinson is a brother of Miss Katherine Stinson.

A record has recently been established at the San Diego flying field, where the cadets in training there flew a distance of 35,000 miles in 72 hours without breaking so much as a support on any of the machines.

Royal Flying Corps Going Back to Canada

The British Royal Flying Corps, commanded by Brigadier-General Hoare, which has been training here since October, will soon be starting back to Toronto, Canada. The British, thousands strong, came to Fort Worth and shared the three American fields here at the invitation of the United States Government. It was a return courtesy for the British invitation last summer to the Americans to train in Canada.

The British will not return to Canada in one body—the movement extending over ten days. After the men in the fields have moved out the headquarters staff will go. With the departure of the English, the fields here will be devoted to Americans.

Liberty Motors Being Shipped Abroad

According to "Automotive Industries", 150 Liberty aeroplane engines were shipped abroad during the past week, and more than seventy had been delivered ready for installation, previous to that time.

Major John Purroy Mitchel, former Mayor of New York City, receiving aero engine instruction at an Army flying field

Aeroplanes Aid Liberty Loan

The big Caproni Italian military aeroplane, piloted by Captains Resnati and D'Annunzio, of the Italian Flying Corps, came to Washington from Mineola, N. Y., "bombing" New York city, Princeton, N. J.; Philadelphia and Baltimore on the way with Liberty Loan literature. The officers will remain in Washington a week to aid in the loan campaign. The Captain's machine was accompanied to New York by six American planes, in charge of Lieutenants E. L. Williams, Charles Ludick, E. B. McCullough, E. O. Barr, H. E. Watson and E. W. Kilgore.

The air fleet made its "raid" on Manhattan under the bluest of skies, raining "buy a bond" paper bombs from the financial district clear up to and beyond the Bronx. The air was filled at times with fluttering papers, which looked not unlike autumn leaves tossed about by the winds. Eager spectators even risked injury by surface cars in efforts to clutch the "bombs" before they could touch the ground.

Captain Resnati in his big Caproni caused all to marvel. He circled high above the Woolworth tower and then took a whirl around one of the American machines before he descended to a point north of City Hall Park and skimmed gracefully over the City Hall, doing a ring above the park.

Then he took a higher air path and zipped along the upper strata of Broadway, dropping Liberty bond literature as he flew.

The American aircraft returned to Mineola in single file after flying above and circling high in the air over the city.

Lieutenant Joseph C. Stehlin, twenty-one years old, who, as the youngest member of the Lafayette Escadrille, on Setpember 7 last, fought three Boche battleplanes 17,000 feet in the air behind the Prussian lines, brought down one of them, disabled another and reached his home station in safety, is going to make a series of flights over the State of New York for the Third Liberty Loan.

Instead of firing a machine gun or dropping bombs to destroy Boches he will scatter thousands of Liberty Loan circulars to arouse the people to buy, buy, buy, and keep on buying.

Lieut. Colonel Vincent on Duty at Dayton

The Signal Corps, Aviation Section, has assigned several of the engineers who were identified with the design of the Liberty motor to duty in Dayton, Ohio, with orders to report to Lieut. Colonel Vincent, Mutual Building, Dayton. Among the officers ordered to report are: Major Howard C. Marmon, Capt. Floyd O. Tobey, Capt. Howard E. Blood, Lieut. Ferel O. Replogle, Lieut. Paul Goldsborough, Lieut. T. C. McMahon, Lieut. William Bernhard, Lieut. Maurice S. Shafer, Lieut. Ernest A. Cawcutt, Lieut. Sam L. Roche, Lieut. Miller B. Heebner, Lieut. Francis E. Engerbretson and Lieut. Lionel M. Woolson and Major Alfred Smith.

Red, White and Blue Circles and Stripes to Distinguish American Machines

Red, white and blue circles and stripes will be the distinguishing mark of Uncle Sam's army and navy aeroplanes, the Signal Corps announced.

The wings of the planes will be marked with a red bullseye. The rudders will be marked with vertical red, white and blue stripes.

Major Hitchcock Commands at Minoela

Within one year from the time he first started taking lessons on the field of flying Major Thomas Hitchcock has been put in command of Field No. 1. Major Hitchcock soon developed into one of the best aviators here. His progress won him his license, this was followed by a commission, and within a short time he was made a captain. His ability asserted itself in many ways and he was promoted to a major. He has now been put in supreme command of all the men at the field, where but so short a time ago he was a beginner.

Major Hitchcock had proved an exceptional scholar. There never was a day when the weather was too cold or windy for him to fly. The only thing left to make his happiness complete now is to receive word that his seventeen-year-old son, Thomas, who was downed by a German some time ago in France, is alive and in a prison camp.

Major Hitchcock replaces Lieutenant Colonel Olin Aleshire, who has been assigned to other duties.

Major Rice Heads American Airmen in Battle

Major Cushman A. Rice, of Willmar, Minn., son of a former Minnesota Lieutenant Governor and member of the Aero Club of America, is commanding the American fliers now operating against the Germans in the great battle in France, according to reports reaching here from the front.

Major Rice has been in France only about a month. Washington friends were greatly pleased to learn of the honor conferred on him. They recalled that he repeatedly was turned down by the War Department last spring when he applied for a commission. He was told he was too old, too big to fly and otherwise unfitted for the service. He served in the army in the Spanish-American War. He fought in South American revolutions, was chief of scouts for General Lawton in the Philippines and took part in putting down the Boxer uprising.

Major Rice finally gave up and enlisted as a "buck" private. Throught the efforts of Senator Knute Nelson the War Department finally waived ground school requirements and sent Private Rice to Mineola Flying Field, where he soon became a sergeant and then graduated several weeks ahead of his class. He was recommended for major by the commander of the flying corps, who at that time said he wanted Major Rice for important work in France.

Before going to Europe Major Rice spent sixty days arranging business affairs in Cuba, where he owns a ranch and rice plantation.

Aviation Corps of 500 to Be Contribution of Siam to Allied Cause

An aviation corps of 500 members will be Siam's contribution to the Entente Allies, according to Frank D. Arnold, formerly chargé d'Affairs at Bangkok, who arrived at San Francisco from Siam on his way to Washington.

"The Siamese army has developed some splendid aviators," Mr. Arnold said. "They seem to take naturally to the work under the instruction of French and Italian experts.

"When I left they were preparing to send over 500 men with a complete quota of aeroplanes, all of foreign construction."

Carolina Aircraft Company Organized

The Carolina Aircraft Company of Raleigh was recently incorporated with an authorized capital of $500,000 and a paid capital of $20,000. The stockholders are Harry N. Atwood, famous pioneer aviator; Howard White, John A. Park and J. M. Broughton. The first craft is to be completed in sixty days.

Reorganization of War Industries Board

Washington.—Under a plan of reorganization announced April 7 by Chairman Baruch of the War Industries Board, the ordering and delivering of war supplies and the management of the big industrial problem facing the country is to be centralized hereafter with the chairman of the board.

The control of industry and production about to be assumed by the board will involve the questions of national price fixing, international pooling of raw materials and the curtailment and possible elimination of less essentials, in all of which the board will have a directing hand.

The central directing agency in the new scheme is the Requirements Division of the War Industries Board and is headed by Alexander Legge. Upon this the War and Navy Departments, the Shipping Board and Food and Fuel and Railroad administrations each will have representatives.

The needs of all departments hereafter will be submitted to this division, which thus will be able to furnish Chairman Baruch with complete information to guide him in determining the general industrial policy of the country, the organization of production and the relocation of industries.

To take charge of each problem of supply a special commodity section has been created. Each section will have card indexed capacity of every manufacturing plant handling this particular commodity, and its orders. It thus will have at hand all the needed information regarding any desired article coming within its jurisdiction and will be able to make a systematic allocation, according to the relative urgency of the needs of the various departments. For example, should the War and the Navy Departments each want a supply of certain shapes of steel, they will lay their demands before the Requirements Division and their purchasing agencies be told just how much to buy and where to place their orders. Purchases of the Allies will follow the same plan.

At the meetings of the commodities section, at which allotment of materials or facilities to fill the requirements is made the representatives of the various supply departments of the Government who are members of the section will have full share.

If any member of a commodity section is dissatisfied with a decision he may, if he wishes, file a protest with the section head and also with the head of his division or department. Then if, for example, he belongs to one of the Government supply departments, his chief may appeal for reconsideration to the War Industries Board, whose decision will be final, subject only to modification by agreement among the chairman of the War Industries Board and the respective Secretaries of War and the Navy and the chairman of the Shipping Board, whichever may be the one interested in the subject.

In cases where it becomes necessary to control an industry in whole or in part by means of allotments, the appropriate section will determine the allotments of materials, commodities and facilities to the several departments of this Government and to its allies and also the extent to which manufacturers or others, whether serving the civilian population or engaged in the manufacture of war supplies, shall be supplied.

When a commodity section comes to make its full report on the allotment of any specific requirements the chief of that section will notify a member of the priorities division of the War Industries Board to be designated for such purpose by the priorities division, who will, with the section chief and the member, consider and tentatively determine the priority rating which such requirements will take when orders therefor will have been placed.

Such tentative rating will be observed by the priorities committee in connection with all applications for priority on orders covering such requirements unless the priorities committee should (because of conditions changing in the time intervening between the time of the fixing of the tentative rating and the application for priorities or other good cause) conclude such rating to be improper; in which event the section chief and each member of the section fixing the tentative rating will be so notified and have an opportunity to be heard before such rating be changed. In the event a change is made the section chief or any member may appeal from such decision in the manner prescribed by that portion of the organization plan of the War Industries Board governing priorities.

NAVAL and MILITARY AERONAUTICS

Key to Abbreviations

AAD—Assigned to active duty.
ADO—Report to Aviation Supply Depot, Dayton, Ohio.
AEF—On duty with the American Expeditionary Forces.
AGC—Report to Aviation Supply Depot, Garden City, L. I., N. Y.
AHT—Report to Aerial Gunnery School, Houston, Texas.
AMV—Report to Aviation General Supply Depot, Morrison, Va.
AOV—Report to School for Aerial Observers, Hampton, Va.
APR—Report to School of Aerial Photography, Rochester, N. Y.
BST—Report to Brooks Field, San Antonio, Tex.
CAF—Report to Carlstrom Field, Arcadia, Fla.
CAG—Report to Camp Hancock, Augusta, Ga.
CAP—Commissioned as Captain, Aviation Section, Signal Corps.
CCI—Report to Chanute Field, Champaign, Ill.
CDT—Report to Aviation Concentration Camp, Dallas, Texas.
CGC—Report to Aviation Concentration Camp, Garden City, L. I., N. Y.
CGS—Report to Aviation Concentration Camp, Greenville, S. C.
CLR—Commissioned as Colonel, Aviation Section, Signal Reserve Corps.
CMV—Report to Aviation Concentration Camp, Morrison, Va.
COL—Commissioned as Colonel, Aviation Section, Signal Corps.
CPR—Commissioned as Captain, Aviation Section, Signal Reserve Corps.
CRI—Report to Chanute Field, Rantoul, Ill.
CSO—Report to the Chief Signal Officer, Washington, D. C.
CUI—Report to School of Military Aeronautics, Cornell University, Ithaca, N. Y.
CWT—Report to Call Field, Wichita Falls, Texas
DAF—Report to Door Field, Arcadia, Fla.
DIK—Report to Camp Dick, Dallas, Tex.
DIS—Honorably discharged from service.
EEP—Report to Essington Field, Essington, Pa.
ELA—Report to Eberts Field, Loanoke, Ark.
EOT—Report to Ellington Field, Olcott, Texas.
FLR—Commissioned as First Lieutenant, Aviation Section, Signal Reserve Corps.
FLT—Commissioned as First Lieutenant, Aviation Section, Signal Corps.
FOB—Report to Fort Omaha Balloon School, Omaha, Neb.
FRF—On duty requiring regular and frequent aerial flights.
FSO—Report to Fort Sill School for Aerial Observers, Fort Sill, Okla.
GIT—Report to School of Military Aeronautics, Georgia Institute of Technology, Augusta, Ga.
GLC—Report to Gerstner Field, Lake Charles, La.
HHN—Report to Hazelhurst Field, Mineola, L. I., N. Y.
JHU—Report to School of Military Aeronautics, John Hopkins University, Baltimore, Md.
JMA—Rated as Junior Military Aviator.
JRC—Report to Jackson Field, Riverside, Cal.
KST—Report to Kelly Field, So. San Antonio, Tex. (When specified in the order, the number of the field is given in parantheses)
LDT—Report to Love Field, Dallas, Tex.
LHV—Report to Langley Field, Hampton, Va.
LTC—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Corps.
LTR—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Reserve Corps.
MAJ—Commissioned as Major, Aviation Section, Signal Corps.
MDO—Report to McCook Field, Dayton, Ohio.
MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MMP—Report to Middletown Aviation Supply Warehouse, Middletown, Pa.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PRC—Appointment to Aviation Section declined; prefers retaining previous commission.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
REL—Relieved from present duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRV—Report to Richmond Aviation School, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
TFT—Report to Taliaferro Field, Fort Worth, Texas. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UCB—Report to School of Military Aeronautics, University of California, Berkeley, Cal.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WFO—Report to Wilbur Wright Field, Fairfield, Ohio.

Note 1. Report to points named for temporary duty in the order given.

Note 2. Report to Atlanta, Ga.

Note 3. Report to district manager of equipment, Detroit, Mich.

Note 4. Report to district manager of inspection, 15 Park Row, New York City.

Note 5. To Washington, temporary duty; then Millington, Tenn.

Note 6. Report to director of training, Bedell Building, San Antonio, Tex.

Note 7. Report to departmental aeronautical officer, New York City.

Note 8. Report to Lieut. Edward Howe, 16 Victoria St., Toronto, Canada.

Note 9. Report to Radio School, Columbia University, New York City.

Note 10. Report to Camp Hancock, Ga.

Note 11. Report to War Prison Barracks No. 2 for duty as censor.

DIMENSIONS OF STEEL TUBE STRUTS

By CARLO MAURILIO LERICI, Electrical and Aeronautical Engineer

Special Correspondent for Aerial Age in Italy

THE accompanying graphs have been prepared in order to facilitate the calculation of the dimensions of such circular and streamline steel tubes as are employed in aeroplane construction. The diagrams give directly the compression permissible for a maximum load of 10 kg. per sq. mm. (13,750 lbs./sq. in.); that is to say, with a factor of safety of six for steel commonly employed having an ultimate strength of 60 kg. per sq. mm. (82,500 lbs./sq. in., or nearly 37 tons per sq. in.). The streamline section tube is that of minimum resistance (Fig. 1), tested by Eiffel and adopted as standard by nearly all the constructors of the world. The fineness ratio of this section is about 3. The ratio of the two moments of inertia I_{xx} and I_{yy} is about 5. It will be easily seen that there is an almost constant relation between strength in compression of circular and streamline steel tubes.

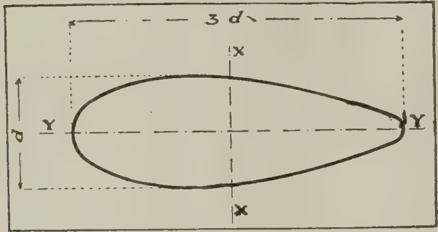

Fig. 1.—Standard section for streamline steel tube.

For the standard type (Fig. 1) I have found that the streamline tube whose section has the external dimensions $d \times 3d$ has the same compressive strength as a circular section tube of the same length and thickness (gauge), having an external diameter = 1.5 d. This factor has formed the basis for the graph (Fig. 2). The following data are given: W = normal compressive load, L = length of tube. The graph shows that for each value of W there are generally several solutions according to the different values of the thickness adopted. In this connection it should be noticed that, in order to attain maximum lightness, one should adopt the minimum possible thickness s. The ratio of s to d should not be less than 1/30.

It should also be pointed out that the condition of minimum weight for streamline tubes exposed to a current of air, as the struts of an aeroplane, is only convenient in machines having a low flight speed. Generally it is possible to so dimension these tubes as to render minimum the power absorbed by their weight and by their head resistance. In the best of modern high-speed machines the total power P absorbed by one meter of streamline tube exposed to the air is given by the formula:

$$P = \frac{dv^3}{10^6} + \frac{34vds}{10^4} \qquad P = \frac{7.25dv^3}{10^8} + \frac{7.85vds}{10^3}$$

d in cm.
s in cm.
v in metres per second.
d in inches.
s in inches.
v in ft./in.

An examination of this formula gives the following results: (1) For machines having a speed of not more than 120 km. per hour (75 m.p.h.) the minimum value of P is obtained by giving the struts a thickness of between 0.8 and 1.6 mm. ($\frac{1}{32}$ in. and $\frac{1}{16}$ in. respectively). (2) For machines of which the normal speed varies between 120 and 100 km. per hour (75 and 100 m.p.h.) the optimum thickness varies between 1.2 and 2 mm. ($\frac{3}{64}$ in. and $\frac{5}{64}$ in.). (3) For speeds between 160 and 200 km. per hour (100 to 125 m.p.h.) the optimum thickness varies from 1.6 to 2.4 mm. ($\frac{1}{16}$ in. to $\frac{3}{32}$ in.). (4) For speeds above 200 km. per hour (125 m.p.h.) the struts should be given the maximum possible thickness, weight having no longer any appreciable influence.

It sometimes happens that one has to depart from these dimensions giving maximum efficiency in order to avoid during flight every vibration that might diminish the compressive strength of struts. For instance, this happens when the frequency of the struts' proper vibration under normal load coincides with or is a multiple of the number of revolutions of the motor. Such a phenomenon of resonance can be countered by modifying one of the dimensions s or d.

The following examples show the method of using the graph:

(1) *Centre Section Strut.*—Streamline section. Steel of 60 kg. per sq. mm. (82,500 lbs. per sq. in.). Factor of safety = 6. Length, 7 ft. Compression in strut, 670 lbs. Thickness $s = \frac{1}{16}$ in. From the diagram it will be seen that the circular tube has an external diameter of 36 mm. ($1\frac{7}{16}$ in.). Streamline tube having same strength, d = 36:1.5 = 24 mm. ($\frac{61}{64}$ in.). As the fineness ratio of the strut is three, the dimensions should be about 1 ft. 3 ins.

(2) *Chassis Strut.*—Streamline section. Steel, 60 kg. per sq. mm. (37 tons per sq. in.). Factor of safety, 6. Length 5 ft. Compression under nomal load, 1,020 lbs. Thickness $\frac{1}{32}$ in. The circular tube indicated in the diagram as being of the requisite strength for this load has an external diameter of 45 mm. ($1\frac{13}{16}$ in.). Streamline tube having same strength d = 45:1.5 = 30 mm. ($1\frac{13}{64}$ in.). As the ratio of s to d is less than 1/30, it will be advisable to adopt a thickness of $\frac{3}{64}$ in. In that case d = 41:1.5 = 27.5 mm. ($1\frac{3}{32}$ in.).

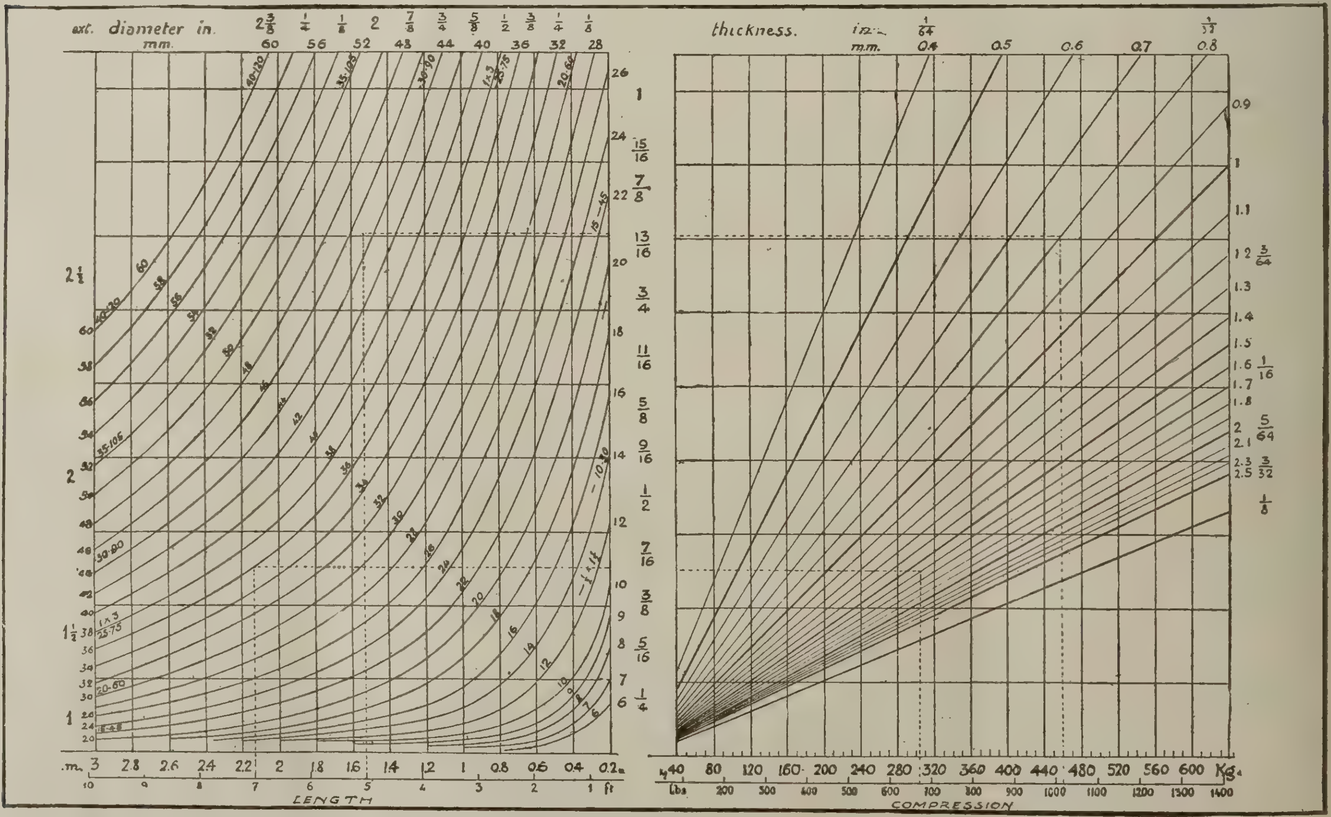

Fig. 2.—Graph showing strength of circular steel tube struts of various dimensions, the material being assumed to be steel of ultimate strength of 37 tons per sq. in. For the section shown in Fig. 1 the values found for circular struts must be divided by 1·5. Other streamline sections would, of course, have different values.

EVERY MILITARY AVIATOR OUGHT TO KNOW WHAT HIS OWN AND THE ENEMY'S MACHINE CAN DO AND HOW THEY LOOK

By HENRY WOODHOUSE

Author of the "Text-book on Naval Aeronautics",
"Text-book on Military Aeronautics", etc.

IN three previous issues the writer pointed out that the Allied Government found it necessary to teach their aviators and students all about their own machines, and as much as possible about the enemy's machines, particularly their appearance. As a basic principle, the aviator is taught that what does not look like one of the Allied machines must be an enemy machine. Therefore, every effort should be made to bring it down.

The anti-aircraft forces are taught the same thing, and that knowledge of the features of the different types of aeroplanes is one of the prime factors in making the anti-aircraft forces efficient.

Lacking that knowledge, both the Allied air forces as well as the anti-aircraft defenses, get confused and permit the enemy to get temporary advantages, which cost the lives of Allied aviators, as well as of the population of the cities which are raided—without mentioning the strategic advantages which the enemy gains through gathering information or surprising the Allies.

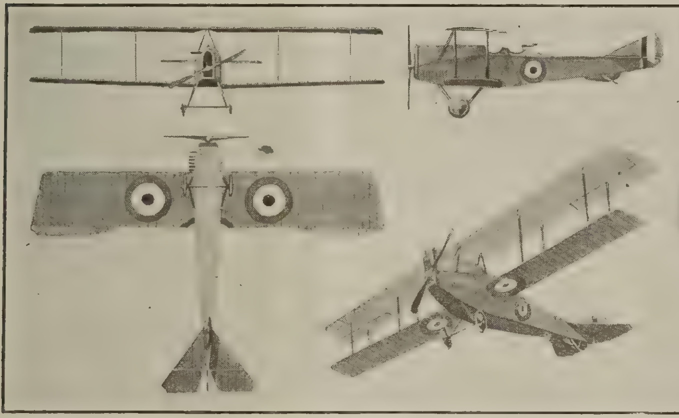
Besides teaching military aviators to know their own and the enemy's machines, what they can do and how they look, the Allied authorities also found it advisable to have continuous progressive changes in their types of aeroplanes.

It was found that German aviators had a certain amount of fear for a new type of aeroplane, because they did not know what it could do and past experience had taught them to beware of appearance. As a member of the Lafayette Escadrille put it: "The Boche was never so surprised as when he attacked a certain type of machine which looked like a two-seater, and got fired on by the third passenger, who was an extra gunner, well equipped with twin Lewises."

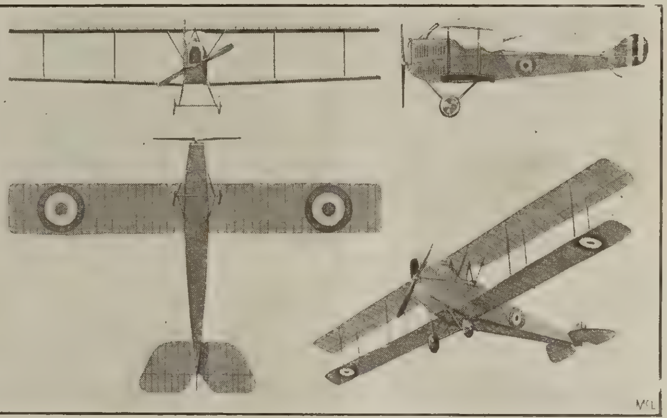
The policy of keeping the enemy "guessing" is good strategy—so long as it does not interfere seriously with production. It can be applied especially in the smaller types of machines used to maintain the supremacy in the air during the daytime on the fronts. It has little value in so far as the large bombing machines used for night bombing are concerned, because the night aeroplanes cannot be seen. It may be deducted from the types of German machines captured that the Germans are also following this policy. They keep up a continuous progressive change of types, adopting the good points of captured Allied machines, adding other points which are suggested by the progress of the science.

The Gothas followed the capture of the Handley-Page bomber, and now the dispatches advise that the Germans are building larger machines equipped with four motors.

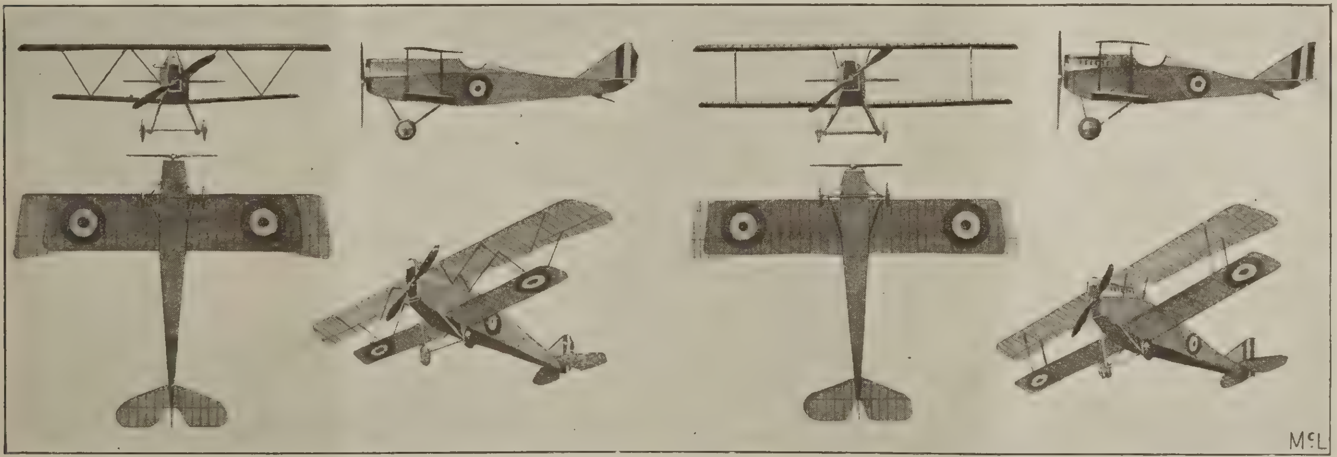
Some of the smaller machines look very much like the French and British machines and it would be hard to recognize one from the other, were it not for the iron cross on the planes. This similarity in characteristics has necessitated closer study of German types and how they look.



Pomilio (Italian). Two place Reconnaissance and Bombardment aeroplane equipped with a 6-cylinder 200 H.P. Fiat engine. Carries a movable Fiat machine gun upon a ring surrounding the rear cockpit, and a synchronized gun firing forward. Ailerons on the upper plane increase in chord as they leave the trailing edge of the main plane. Trailing edges of lifting and controlling surfaces are fluted. The upper part tail skid is enclosed in a sheet aluminum streamline covering which is easily discernable from the side. Upper plane flat in span, but lower sections have a slight dihedral. The Pomilio Co. also builds a fast Scout, which cannot at this time be described.



S. I. A. (Italian). A two-place Combat machine which has recently proven its remarkable power of endurance in a non-stop flight from Turin to London and a 1000-mile flight from Turin to Naples and return. It is equipped with a 6-cylinder Fiat engine, with an exhaust stack leading to the upper plane. Both planes have an equal span. Central braces from the fuselage to upper plane are in the form of the letter W. Trailing edges of plane surfaces are straight and not formed of wire, as in many other Italian aeroplanes. A balanced rudder is used.

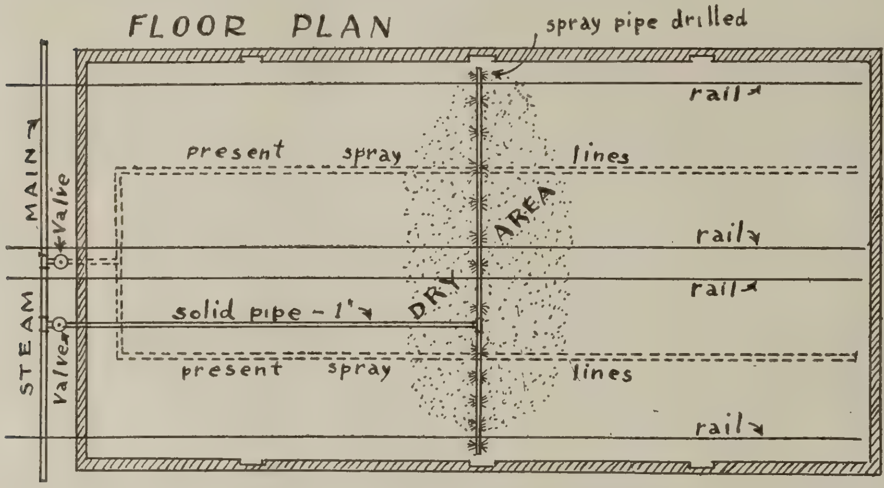


S. V. A. (Italian) Fighting Scout. Several types of scouts are turned out by Gio Ansaldo & Co., of Genoa. The two illustrated above are said to have been used extensively. Both machines are equipped with 210 H. P. "SPA" engines. In the machine at the left the tubular steel struts are inclined laterally, a structural feature which is an identifying characteristic. The body is very deep and proportionately narrow, especially toward the tail. The tail group is somewhat similar to the French Spad, although the tail plane of the S. V. A. is smaller. The machine at the right has a single set of vertical struts at either side of the body, and the struts from fuselage to upper plane slope outward at their top. In both machines, the lower plane has a slight dihedral. There is no stagger nor sweepback. The usual two wheel landing gear and a spring steel tail skid are employed. These machines carry a machine gun at the side of the fuselage, synchronized to fire through the propeller path.

DRY KILNS—A SAFETY FACTOR IN AEROPLANE CONSTRUCTION

By VICTOR R. JOSE, Jr.

"WOULD you want to be the cause of even one United States aviator crashing to earth in a pitiful wreck because the wood you built into his aeroplane snapped in midair?" I recently asked a manufacturer who wanted to know why he should change his methods of drying lumber.



"Well, if that is the situation, we certainly must change our kilns and system. Make your recommendations; results, not costs; in they go!"

With that spirit of patriotism manufacturers are facing the greatest change in the methods of drying of wood since the dry kiln supplanted the smoke kiln. The aeroplane has forced a tremendous awakening in the lumber industry which gives promise of big results and success after the war as well as those already apparent and for immediate use.

The old method was one of extracting the moisture from the wood; literally baking it out; drying the wood. Consequently there developed the commercial "Dry Kiln." The only idea at that time was to get the water out—turn on a supply of heat and pull the water out fast. No one ever weighed a board or thought of examining a sample piece. As a matter of fact, no one in charge of the kilns would have known how because the drying was entrusted to any yard man or laborer who could turn a steam valve. If the lumber had been in "long enough" it was time to pull it out. Whether it contained 12% of moisture or was bone dry only mattered in so far as that the bone dry usually milled easier. You see all this was even before Wrights had reached that preliminary stage of invention where the genius is accepted as a "nut."

There being an abundance of lumber in this land of limitless resources, only the best need be used. There was always a constant stream of fresh material coming in so that the mushroom piles in the yards, tilting this way and that, sprang up above the mill yard fences on all sides. The supply was always ahead of the demand and so the lumber stood in the air and seasoned for months before its turn came. Practically every bit that went into the dry kilns had been previously seasoned in the air-seasoning laboratory of that versatile specialist, "Mother Nature." Ask any number of the older kiln men whether this preliminary drying is necessary and they will chorus "yes." Ask any number of them why, and they will solo any number of reasons.

A meddler came along one day and compared the meager available data. He noted the different systems in use, and he asked about the different temperatures recommended for the drying operation. But success brooks no meddlers; figuring costs had not yet reached the dry kiln out on the edge of the plant. The meddler was soon suppressed.

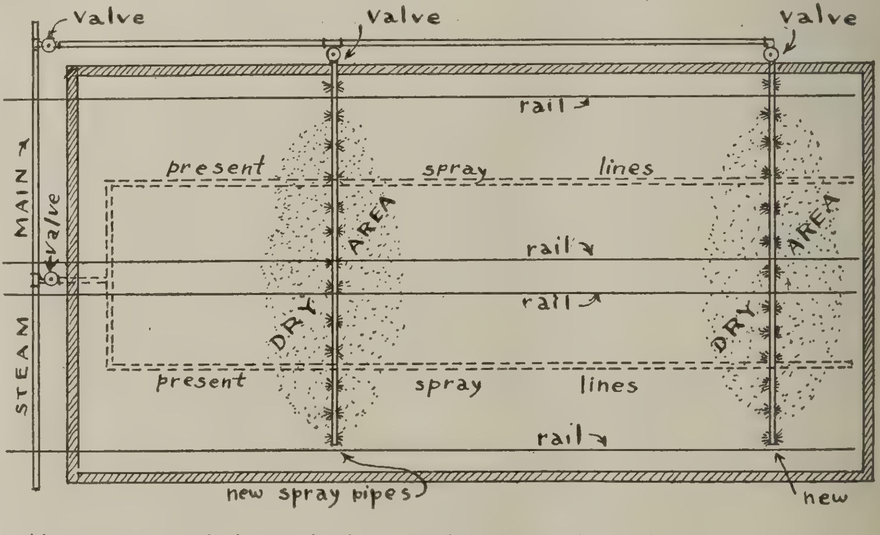
Along came an insistent domineering chap called "Mars." And in his wake came buyers from the nations abroad. They bought up all the available stock of lumber which had been seasoned by "Mother Nature," and the piles flattened even as they had grown. Spruce, birch. quarter-sawed oak, went as tho rubbed off of a slate. And when "Mars" demanded of Uncle Sam that he build aeroplanes—thousands of them—the kiln operators gasped.

Could virgin spruce and oak, green from the saw, be dried at all? How fast could it be done? How fast *should* it be done? And at what temperatures? These were only the major questions of an endless series that presented themselves.

Then someone added to the burden by "wondering" whether different temperatures and methods might not affect the cells and the strength of the lumber; for when you get down close and look through a miscrscope you are dazed by the omniscient foresight revealed in the wonderful construction of those minute cells, and walls, and passages.

The demand was for supreme strength, for the precious lives of the "Cavalry of the Air"—*our* Cavalry—depended on thin, frail, strips of wood of lightest possible weight and greatest strength upon which the burden rested in flight. And with this sobering demand, and the abnormal conditions with which to meet it, new instruments or at least new methods were imperative. Clear thinking immediately reached this conclusion.

Scores of experiments were made. They developed the conclusions that high temperatures weakened the strength of the wood. Its power to resist shocks was lowered; and the shocks in battle flight are many. Impact tests, vibration tests, bending and strength tests of various kinds, developed curves showing wide differences in specimens seasoned at different temperatures. It was found that spruce should not be started higher than 120 degrees F., and that this temperature should be built up to a maximum of 145 degrees, with the increase gradual according to the amount of moisture in the wood from time to time and *not* according to an arbitrary chart. The speed of drying becomes an individual problem in each case. Instead of an arbitrary number of days for drying determined upon loading the kiln, the drying is determined by the actual reduction of moisture in the lumber.



The moisture content of the lumber is definitely determined in small test discs taken from representative boards. Weighed when cut and again after being thoroughly dried in an electric oven, the loss of weight shows the loss of moisture. From

Officers of Aircraft Manufacturers' Association, together with officers of the Standard Aircraft Corporation. Top row, left to right: B. L. Williams, former secretary, Aircraft Manufacturers' Association; John P. Tarbox, Curtiss Engineering Corporation; Fay L. Faurote, Curtiss Aeroplane and Motor Corporation. Middle row: D. C. Meenan, treasurer, Standard Aircraft Corporation; A. B. Bliss, Burgess Company; A. C. Pope, manager, Wright-Martin Aircraft Corporation of Los Angeles; J. G. Ridenour, vice president, Wright-Martin Aircraft Corporation; C. H. Day, chief engineer, Standard Aircraft Corporation. F. G. Barnard, production manager, Burgess Company; F. W. Atkin, Dayton-Wright Aeroplane Corporation. Lower row: B. S. Foss, B. F. Sturtevant Company, secretary of Aircraft Manufacturers' Association; H. B. Mingle, president, Standard Aircraft Corporation, and treasurer of Aircraft Manufacturers' Association; Frank H. Russell, president, Aircraft Manufacturers' Association; R. I. Ware, Thomas-Morse Aircraft Corporation.

a great number of these, taken from each load, the average moisture content of each and any board in the kiln charge is computed.

Carefully weighed sample pieces, two feet long and of average condition, and three for each 5,000 board feet in the kiln, are placed at various points in the piles. Each one being weighed, the amount of its weight which represents moisture and not wood substance, is computed on the basis of the average obtained from the small discs. These two-foot samples dry under the same conditions as the rest of the charge. They are weighed each day to see how much moisture they are losing, and their condition governs the decisions to advance or retard the temperatures of the kiln.

Experiments also showed that the tendency of the lumber to dry on the surface must also be met and retarded to prevent such conditions as "case-hardening," a condition in which the outer portion drives under stress and sets up a strained condition of the fibers when dry. It was found that "case-hardening" was affected by the humidity of the air as it circulated against the surfaces of the lumber. As in the case of temperatures, so here again a schedule was evolved on the basis of moisture content, running from 80 per cent at the start to 33 per cent at the end. (For oak the range is temperature 105 to 135 and humidity 85 to 40.) Repeated examinations of the air in the kiln are made at frequent intervals by means of instruments known as "Hygrometers," "Hygrodeiks," etc., from which the relative humidity is determined.

Recording thermometers are provided for each 36 feet of length of kiln and on charts in the operating room the patient pen automatically marks the exact condition for every minute of the day and night.

Watching the records as they go down on his chart from hour to hour—weighing samples, reading Hygrometers and "mixing brains with his hands"—the operator controls the evaporation and conditions so that the movement of the water from within the tiny cells and the cell walls is produced and accelerated in such a way as to cause no injury to the structure and no loss of precious strength.

Even in piling the lumber the old haphazard slapstick method has given way to careful stacking with a view to expediting circulation and controlling its course.

The strength of every board is being jealously guarded through the entire process. When the lumber, "on its way to the clouds," leaves the kiln seasoning department it is fit for the world's finest fighters. A tremendous increase in efficiency and safety has been added by modern seasoning.

Government inspectors over every kiln assure the rightly anxious flyer that only the fit will be sent out for his use.

Suggestions for Dry Kiln Operators

Humidity plays such an important part in the drying of lumber for aeroplane uses that it needs the very closest attention. Too much humidity causes no sleepless nights, but the demons of "case-hardening" and "hollowhorning" walk the bed rail at the suggestion of a drop in the relative humidity of your kiln.

In long kilns this problem often becomes quite serious upon close examination of the kiln. Investigation of different sections of the kiln, as, for example, near flues in external ventilating kilns, will often disclose "pockets" or "spotted" areas.

"Pockets" often exist, although the regular points for taking Hygrometer readings show proper humidity readings. For example. in the areas near a ventilating flue, the air, which has passed through the lumber and picked up moisture, is being pulled out so fast that there remains only the dry, hot air coming up through the heating coils. The relative humidity of dry, hot air is, of course, very low. Consequently in that immediate neighborhood a pocket of low humidity exists. Often this affects a whole truck of lumber at that point. This same condition may also affect several points.

The whole kiln can be reached by means of the steam spray lines which usually run the entire length of the kiln. But the fact that they do run the entire length makes them impractical for temporary uses on small local areas.

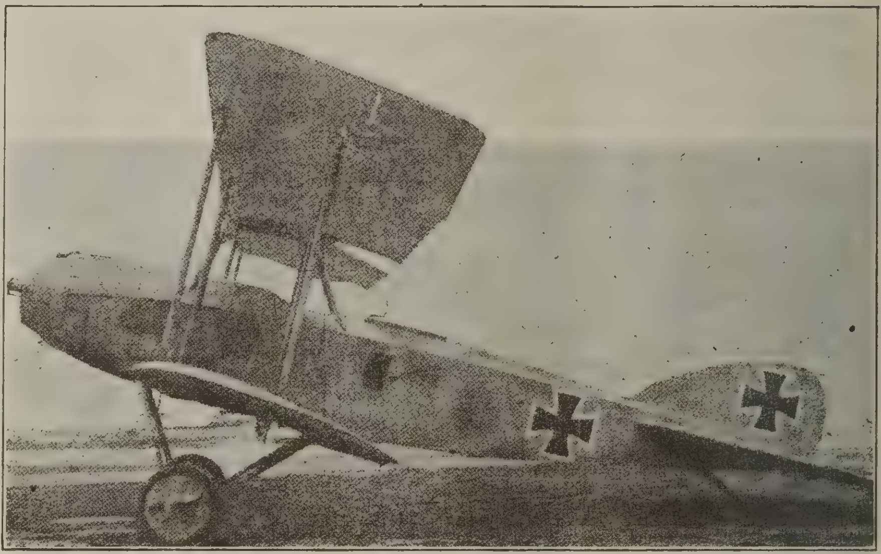
A simple remedy is applied by tapping in on the main steam line with a small spray line; usually a one-inch line is sufficient. Control this line by means of a small hand valve. Run it to the point where the "pocket" occurs, and then across the "pocket area." Along its entire length across the "pocket area" drill 3/16" spray holes on the bottom on about 8" centers. Whenever the pocket occurs turn the control valve for this individual line and let in enough spray to properly humidify the air. If necessary this spray can be left just barely "sizzling" continuously. Control over one area is thus provided without turning steam into the entire kiln, an operation which destroys the working balance of temperature, general humidity and often of circulation.

THE ALBATROS TYPE "CV" FIGHTER

(Continued from page 212)

IN the preceding article on the Albatros Fighter, published by courtesy of "Flight," scale drawings and detail sketches (figures 1 to 7) were shown. This week we deal principally with the fuselage and tail plane.

Fig. 8 shows, in side elevation and plan, the general arrangement of the fuselage, and should, in conjunction with the various sections and key diagrams, explain fairly clearly the general layout of the body. It will be noticed that in plan the sides of the body are straight from the tail post forward to the pilot's cockpit. For ease in manufacture it is an advantage that the ribs of the tail plane should be at right angles to the spars, and in order to effect this it is necessary that the sides of the body should be parallel for the length of the tail plane. Since, however, to provide for this the longerous would have to be changed from a converging direction to a parallel one which would necessitate a somewhat sharp bend in them at the point where the tail plane commences, and as, moreover, the depth of the tail plane is not the same as that of the body except at the extreme rear, a different



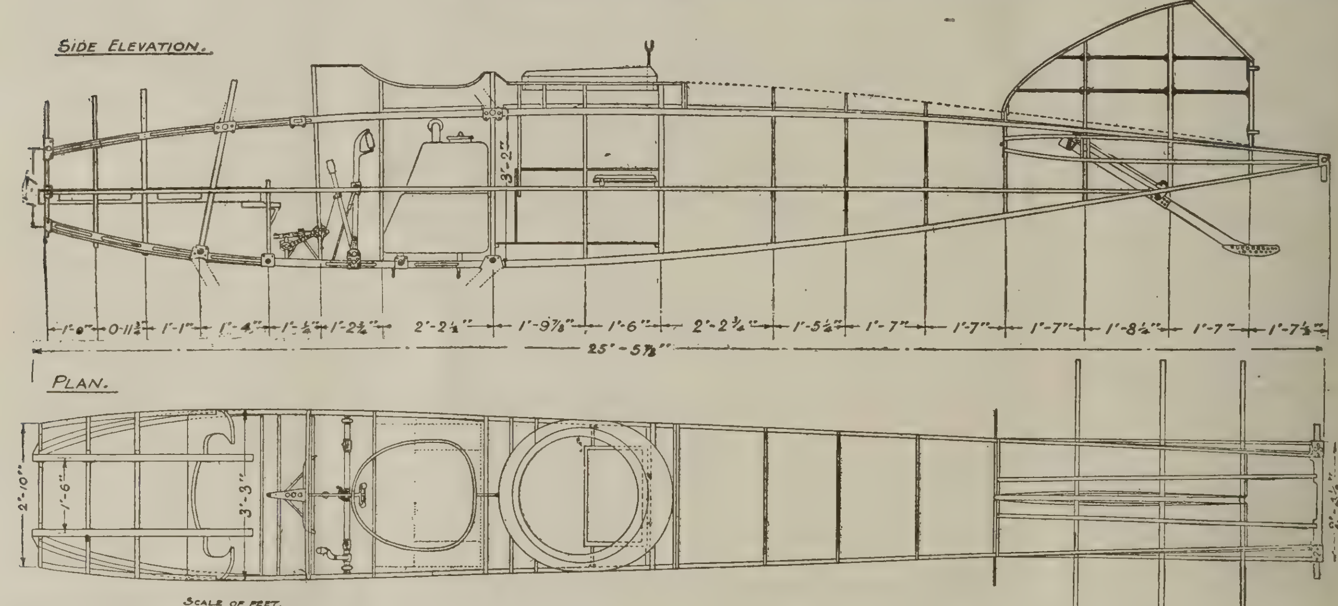


Fig. 8.—General arrangement of the Albatros body. Side elevation and plan to scale.

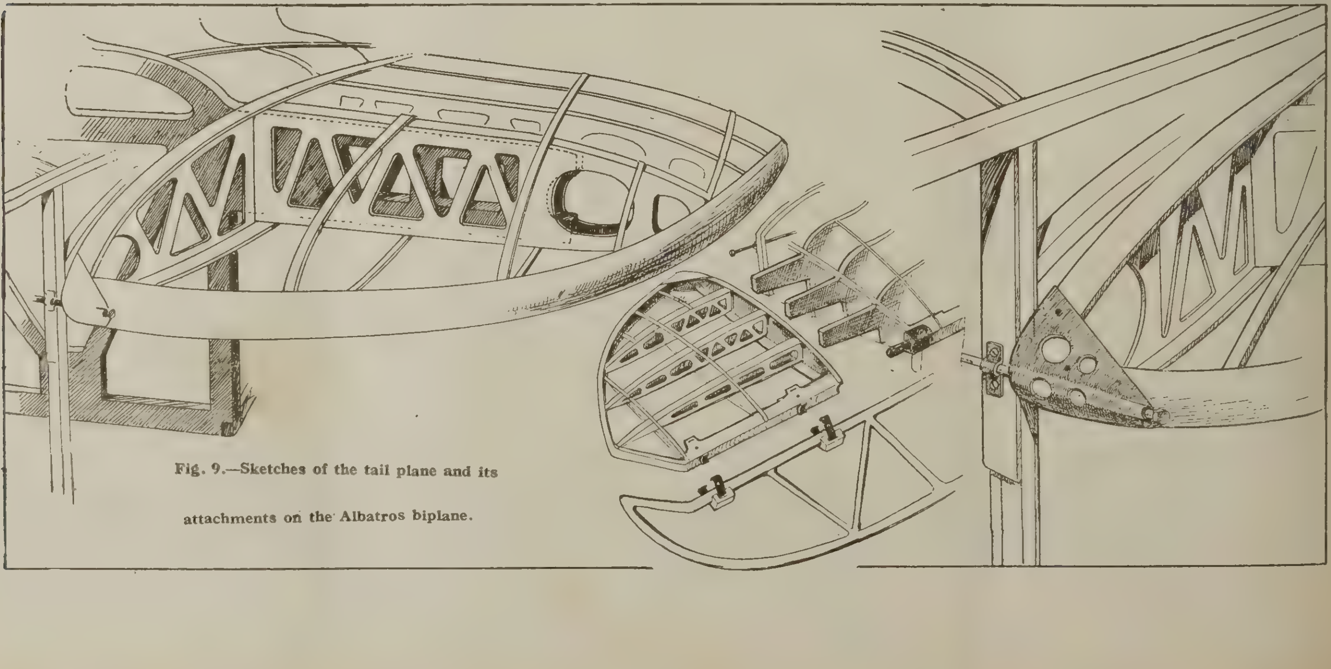

Fig. 9.—Sketches of the tail plane and its attachments on the Albatros biplane.

course has been followed. From the point where the tail begins two extra longerons on each side have been built into the bulkheads of the body. These two short longerons have, in plan, a direction parallel to the line of flight, while the main longerons continue on their converging course. This arrangement is indicated in the plan view Fig. 8. In side elevation the short longerons, against which lie the inner ribs of the tail plane, have the same curvature as the tail plane. In this manner the lines of the rear part of the body are not spoiled, while an easy flowing curve is provided for running the tail plane into the body. The arrangement will be further made clear by reference to Fig. 1, page 224.

Reference has already been made to the peculiar attachment of the tail planes to the body. The sketch at the top of Fig. 9 shows in perspective this attachment, which is also illustrated in the diagram in the bottom left-hand corner of Fig. 9. The bulkheads of the body are extended outwards to form cantilever beams which support the tail plane. There are three of these cantilever beams, while further support is provided for the tail plane leading and trailing edges as indicated in the sketches. The spars of the tail plane are of the box type, built up of ash flanges with thin three-ply sides, cut out for lightness. These spars are so proportioned that they fit over the cantilever beams, which do not, it will be seen, run right out to the edge of the tail plane, but are finished off just outside the second tail plane rib. No external bracing of the tail plane is provided, the depth of it and the method of mounting being relied on for the necessary strength.

To provide against the tail plane sliding off its cantilever supports it is secured at the leading and trailing edge. The former attachment is indicated in the bottom right-hand corner of Fig. 9. A sheet steel shoe fits over the corner of the leading edge and inner rib, and through this shoe a long bolt passes, which runs across the body to a similar shoe on the other side. In Fig. 10 is shown the rear attachment of the tail plane. A sheet steel box surrounds the corner of the fuselage. Welded to this box is a short tube which fits into a circular recess in the end of the trailing edge of the tail plane. As the elevator tube runs right across and is fitted with collars bearing against the sides of the clips that form the bearing for the elevator tube, the trailing edge of the tail plane is prevented from slipping outwards.

The manner employed of forming bearings for the elevator is indicated in the diagrams of Fig. 10. A steel strip is bent over the tube, and its two free ends are bent over and fit into slots in the trailing edge of the tail plane. Each clip is then secured to the tail plane by a vertical bolt as shown in the diagram. The trailing edge of the tail plane is spindled out to a semi-circular section as shown, and a curved metal distance piece is screwed to this trailing edge or spar, so as to form the second half of the bearing of which the bent steel strip forms the other half. To remove the elevator the bolts securing the clips are undone; the clips are then bent outwards until their free ends clear the slots, when the elevator can be removed bodily.

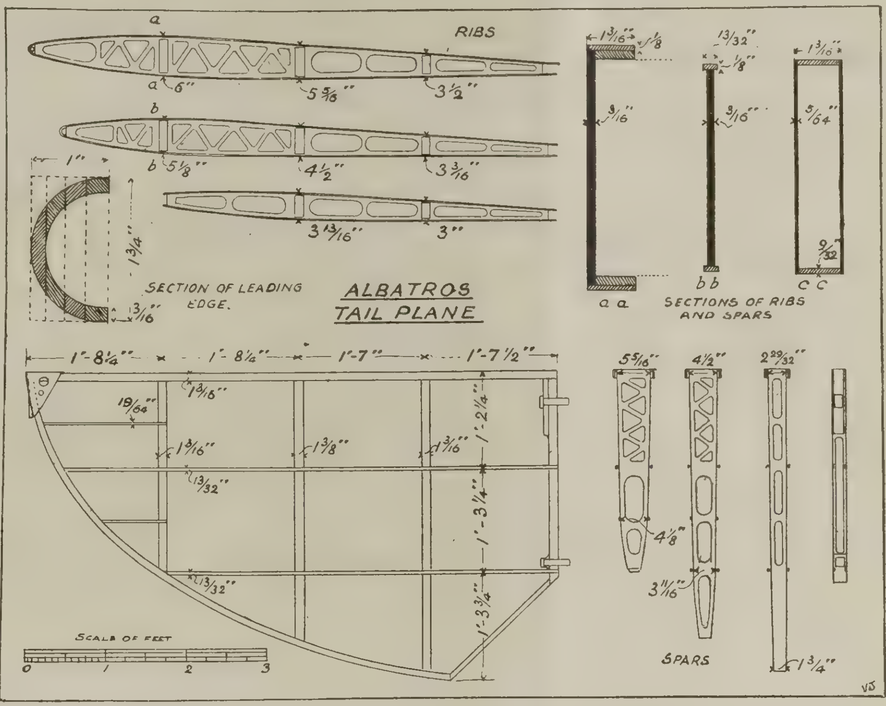

Fig. 11.—General arrangement and dimensions of the members of the tail plane on the Albatros biplane.

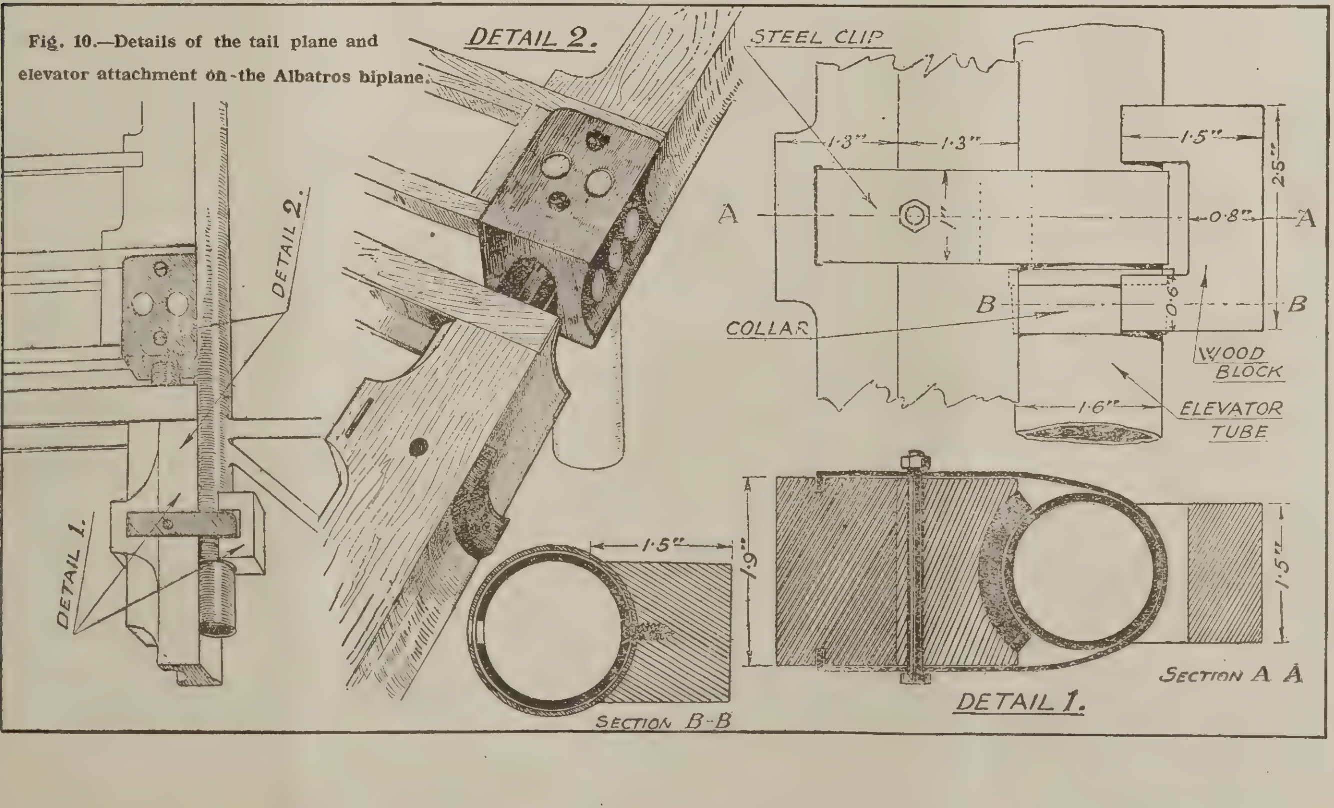
As the elevator is built of steel tubing throughout, wood blocks of the shape shown in detail 1, Fig. 10, are employed for attaching the fabric covering. These blocks span over the steel strip bearings, and are secured to the tubular leading edge of the elevator by screws as shown in section B-B. A hole in the opposite wall of the tube serves for the insertion of the screwdriver.

Under the horizontal stern post of the body are two short tube stumps, closed at their lower ends. The object of these is not at first apparent, since they appear too short to protect the elevator, but when it is remembered that the Germans favor transportation by road, trailing the aeroplane behind a lorry, it becomes at once evident that these stumps serve to support the stern of the body on the floor of a lorry while the machine is trailed behind on its own wheels.

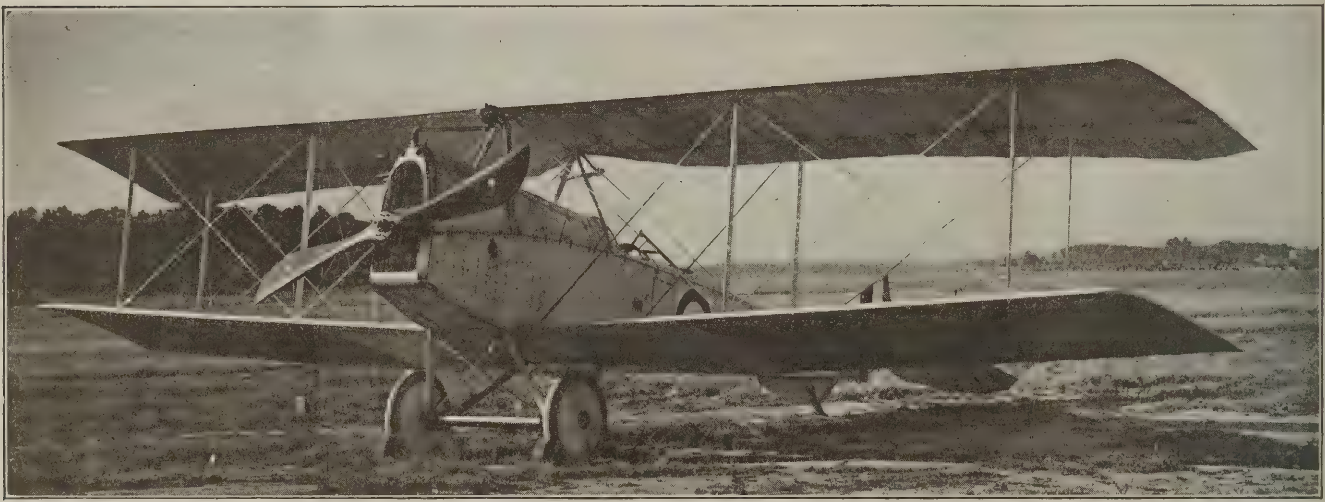
As regards the remaining details of the tail of the Albatros little need be said, as they are fairly evident from the plan and sections of Fig. 11. It will suffice to point out a rather ingenious construction of the leading edge of the tail plane. In plan the tail plane, it will be seen, is roughly semi-circular, and its leading edge therefore has to be shaped to this curvature. As an ordinary strip of solid spruce spindled out to a semi-circular section would scarcely be strong enough for this work, a different method has been employed. It appears that originally the leading edge of the tail is made up of four laminations of ash, having, of course, their grains running in slightly different directions. The rectangular section spar thus formed is then spindled out to a semi-circular section, as shown in the diagram, leaving the impression that the leading edge is made up of seven thin strips of wood glued togeaher. The resulting leading edge appears to be one of great strength, while at the same time being quite light.

(To be continued.)

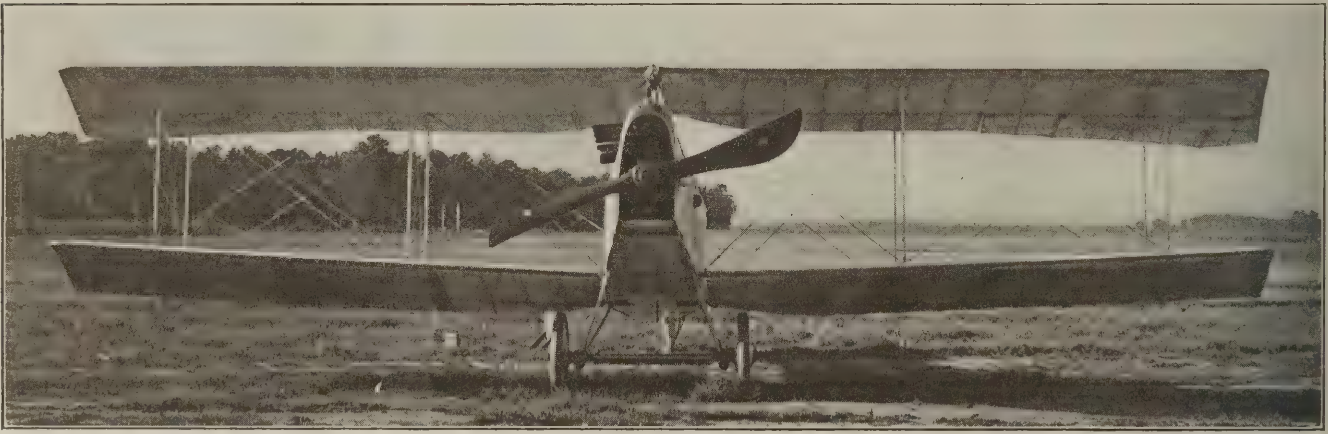
Fig. 10.—Details of the tail plane and elevator attachment on the Albatros biplane.



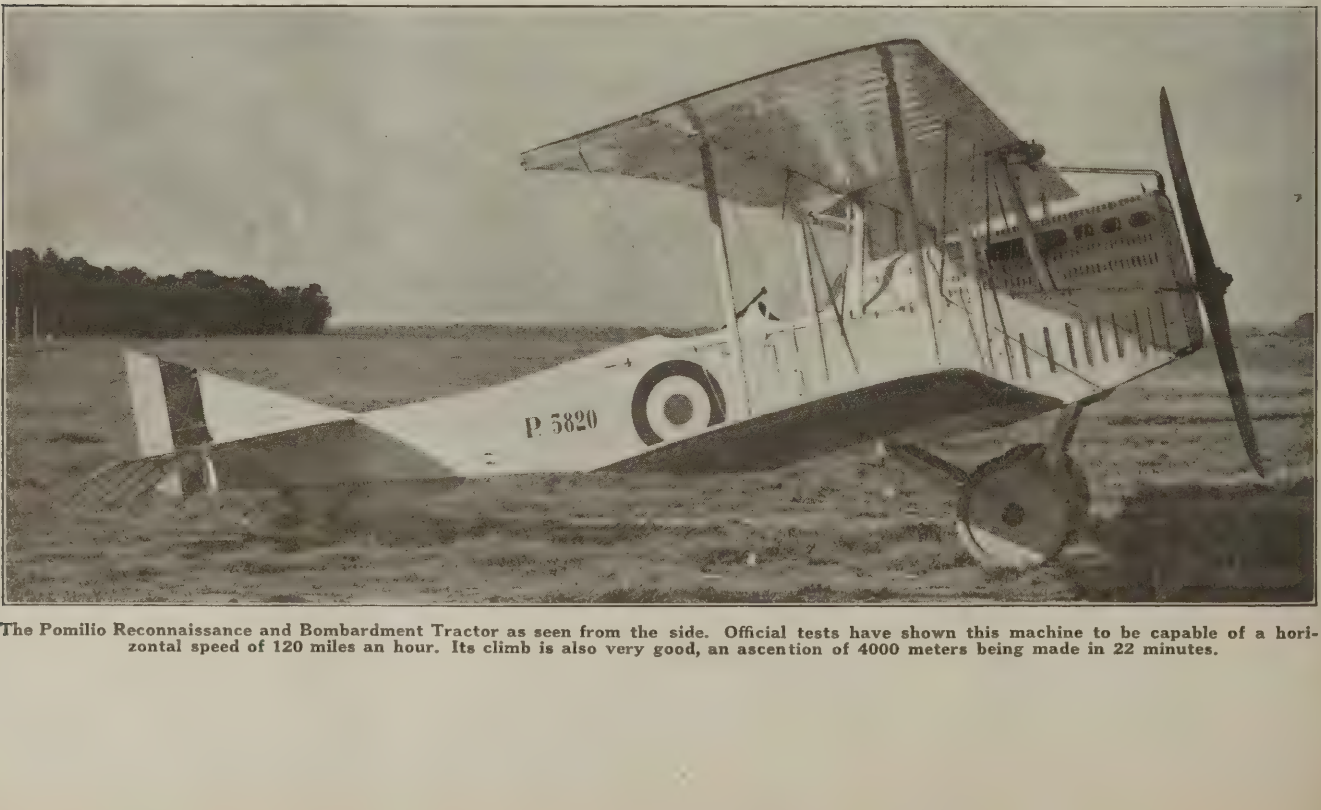
THE POMILIO RECONNAISSANCE TYPE TRACTOR



The latest Pomilio Reconnaissance and Bombardment Aeroplane, one of Italy's powerful weapons of defense against the Austro-Germans. Apparatus is carried for the release of bombs, and a movable machine gun is mounted at the rear cockpit.



Front view of the Pomilio Aeroplane. It has a 6-cylinder 200 H.P. Fiat engine and a Fiat machine gun. Wing span, 38'-0"; height, 10'-0"; overall length, 30'-0".



The Pomilio Reconnaissance and Bombardment Tractor as seen from the side. Official tests have shown this machine to be capable of a horizontal speed of 120 miles an hour. Its climb is also very good, an ascention of 4000 meters being made in 22 minutes.

THE SENATE INVESTIGATION OF THE WAR DEPARTMENT—AIRCRAFT PRODUCTION

Majority Report Urges One Man Control of Air Program

THE Committee on Military Affairs of the Senate, on April 10, submitted the following report on the aircraft situation:

"The Committee on Military Affairs, being engaged under authority of the Senate in an investigation of the War Department, and having taken much testimony, herewith submits the following report in the matter of aircraft production, together with certain recommendations:

Training Schools

"The Signal Corps has established and is now conducting 20 aviation training schools in the United States. Four additional schools are in process of construction and are expected to be finished in June next.

"The aggregate capacity of the schools now in operation is something over 3,000 cadets. One thousand nine hundred and twenty-six have thus far been graduated from this primary training course and commissioned as reserve military aviators. Very few of these have received their advanced training in this country.

"In addition to the above, the Signal Corps, acting upon the invitation of the several entente Governments, dispatched some 1,200 cadets to England, France, and Italy last year, who were to receive primary and advanced training in aviation schools of those countries. The experience of a great many of these men has been most unfortunate in that at some of the schools a very serious delay has occurred in providing them with the training planes, which it was expected would be manufactured in foreign factories in sufficient number. As a result, several hundred of the American cadets have been practically idle and have made no progress. About 450 of them are reported as having completed the primary training after long delay. The Signal Corps is giving serious consideration to the advisability of bringing the remainder back to the United States to be trained. With the exception of this severe disappointment, the primary training of our aviators, according to the testimony of the aviation officials, appears to be progressing favorably. The health record of the schools is excellent and the fatalities arising from aviation accidents, while always distressing, appear to be less frequent than in the schools of our allies, according to the testimony of the Chief Signal Officer.

Training Planes

"For some time after the inception of the work the output of primary training planes in this country for use in our schools gave ground for grave concern. In recent weeks, however, the output has been greatly increased and there seems to be no doubt of the Signal Corps having an amply sufficient number in the future. On April 1, 1918, 3,458 primary training planes had been completed. The planes are of two standard types developed for the purpose and are equipped with Curtiss and Hall-Scott motors, respectively. The advanced training planes are being turned out in accordance with the schedule and estimates laid down at the inception of their manufacture. In advanced training planes four types are being made, the total number up to date manufactured being 342. In these planes three types of engines will be used, of which 965 have been completed. These include Gnome, Le Rhone, and Hispano Suiza, all of foreign design but American manufacture. The Liberty motor is not suitable for use in these planes.

The Liberty Motor

"It is apparent from the evidence that the 12-cylinder Liberty motor is just emerging from the development or experimental stage. Since the original design and the setting up of the first completed motor in July, 1917, a large number of changes have been found necessary, many of them causing delay in reaching quantity production. Within the last two months changes of considerable importance have been made which, it is hoped, will make the motor serviceable for combat planes of the defensive type, and for bombing and observation planes. It is not designed for and can not be used in the swift, single-seater fighting machine. A few of the motors are being flown in appropriate machines. These reports, as recited to the committee, indicate that with the latest changes the motor will be satisfactory for the character of work expected of it and that it bids fair to hold its own with foreign motors of similar power, weight, and purpose. For the campaign of 1919, the Liberty motor must undoubtedly be further improved in order to keep up with the evolution constantly going on along the front. The motor as now manufactured is of the direct-driven type, a type which has limits of usefulness in heavy machines.

"Steps are being taken in the designing of a geared drive, in order that the usefulness of the motor may be further extended and further improvements attained. Twenty-two thousand five hundred Liberty motors have been ordered, 122 have been completed for the Army, and 142 for the Navy. Four have been shipped overseas. Some of those already delivered are being altered to overcome the defects ascertained during the last few weeks. It is understood, however, that these alterations will consume but a very short time. The production of Liberty motors to date is, of course, gravely disappointing. The testimony shows that experts of the highest reputation and experience have, since last July, repeatedly warned the officials of our Government that the perfecting of a newly designed motor must inevitably involve many months of painstaking experiment accompanied by many setbacks and disappointments. In spite of the unanimous testimony of motor experts along this line, the Government officials having the manufacture of the Liberty motor in charge have made the mistake of leading the public and the allied nations to the belief that many thousands of these motors would be completed in the spring of 1918. Information of this sort, not borne out by the facts, has been injurious, and its constant dissemination the committee regards as misleading and detrimental to our cause.

Combat Planes

"The production of combat planes in the United States for use in actual warfare has thus far been a substantial failure and constitutes a most serious disappointment in our war preparations. We had no design of our own; neither did we adopt any one of the European designs until months after we entered the war. Much time was consumed in discussion as to types. Innumerable changes in designs and specifications of the types finally decided upon have cost further delay. In all, five types have, at one time or another, been adopted. Two of them have been abandoned after the expenditure of much time and money. The three remaining types still left upon our program are now in the course of manufacture. Of these, the largest and most powerful is the Handley Page heavy bombing machine, designed to carry as many as six men, eight machine guns, and a heavy load of bombs, and to be driven by two Liberty motors. The history of the negotiations for the adoption and manufacture of this plane afford a remarkable illustration of procrastination and indecision, too long to recite. Suffice it to say that the designs and specifications of this plane which had been used with marked success by the British and placed in production by that Government, were offered to our officials as early as May, 1917. The testimony before your committee shows that the Signal Corps finally decided upon the manufacture of a number of sets of parts of this machine about January 1, 1918. Eventually the finished and tested parts will be shipped to England, where they are to be finally assembled in factories now being prepared for this work. Officials of the Aviation Section of the Signal Corps testify that they do not expect the completion of the first set of parts in this country before the month of June, 1918.

"Another type of combat plane, known as the De Haviland, is included in our program. This machine habitually carries two men, four machine guns, a moderate load of bombs, and other apparatus and is to be driven by one Liberty motor. Fifteen have been completed; 1 has been shipped to France; the remaining 14 have been very recently completed in this country. Some of these have been tested, propelled by a Liberty engine, and appear to have given satisfaction. The third type upon the program is known as the Bristol fighter. This machine is lighter and faster than the De Haviland. Its speed is expected to be in the neighborhood of 125 miles per hour. It is what is known as a reconnoissance machine. Another term which might be properly applied to it is "defensive fighter." It carries two men, four machine guns, and is driven by one Liberty motor. The decision to make this type was reached on November 7, 1917. The manufacturers completed the first of these machines during the week ending March 30, 1918. The machine was tested once during that week with a Liberty motor, and, according to the testimony of the aviation officials, met its preliminary test successfully. This machine, a few hours after its flight, caught fire while standing upon the aviation ground and was entirely destroyed. The officials of the Signal Corps assured the committee that another machine would soon be finished by the manufacturer and that if it met the tests satisfactorily quantity production might be expected within a reasonable period. The testimony as to this machine was given on April 2, 1918. This completes the list of machines now under manufacture and constitutes a correct statement of the situation in this country as of April 1, 1918. In addition to the American production of engines and aeroplanes as herein set forth, considerable orders for combat aeroplanes and engines were last summer placed with European manufacturers by Gen. Pershing, and we have furnished quantities of material and numbers of mechanics to aid in their construction.

"Your committee has full information as to the number and quantity of machines and engines ordered here and abroad but does not feel justified in stating the number in this public report. The facts contained in this report are drawn from the testimony of the Chief Signal Officer, Gen. Squier, Col. Deeds, and Mr. Potter, the chief of the Equipment Division of the Aviation Section of the Signal Corps, and are confirmed from other sources official and otherwise.

"Your committee, being devoid of technical knowledge of motors and aeroplanes, does not undertake to point out in detail engineering and manufacturing errors which may have been committed and which, in part, may account for this gravely disappointing situation. Your committee, however, is convinced that much of the delay in producing completed combat aeroplanes is due to ignorance of the art and to failure to organize the effort in such a way as to centralize authority and bring about quick decision. A certain aloofness in dealing with persons possessing information based upon experience, an apparent intention of confining the actual production to a restricted number of concerns, and a failure of the officials in charge of the work to grasp the situation in a broader way and seize upon the best approved foreign engines and planes and proceed promptly to build as many as possible for the campaign of 1918 has contributed to the failure. It is greatly to be regretted that the statements of Government officials have misrepresented the progress of the aviation program. This has misled the public, and your committee, cognizant of the facts, has, in the performance of its duty, made this report to the Senate.

"Your committee believes that production of aircraft should be controlled by one executive officer, appointed by the President and responsible to him. He should be assisted by a corps of the best aircraft engineers and designers possible to obtain, both European and American. The matter of production should be taken out of the hands of the Signal Corps entirely, and no man who has any near or remote interest in a company manufacturing airplanes or engines should be permitted to act as adviser or be in authority. While we are developing American aircraft and American engines we should temporarily, at least, procure an abundant supply of approved types of aircraft and engines of European design.

"Further, it seems to the committee that every encouragement should be given to the development of aircraft and that any action which retards progress, such as trust agreements or the prevention of those developing machines from flying, under proper restrictions should be removed.

"The committee also believes it to be its duty to point out that thus far no broad plan looking to future development has been laid down by the authorities. Warfare in the air is still in its infancy and it is inevitable that rapid changes will take place in both engines and planes. It is essential to our success that those in charge of the American aviation development shall be constantly looking ahead and devising plans for a continued expansion of the program, as well as the development of new types of engines and planes."

THE MINORITY REPORT

The minority report follows:

"We do not believe that the report of the majority of the Senate Military Affairs Committee on the aviation situation shows a proper estimate of what is being accomplished or that it is sufficiently complete to give an accurate impression of the facts.

"Soon after the war began the Signal Corps arranged with the French Government for the making of 6,100 combat planes at a total cost of $127,000,000, the planes to be produced as rapidly as American fliers could be trained to operate them. As the American aero squadrons reach the front ready for duty, battle planes are being supplied them under this arrangement. To aid in this foreign manufacture of planes for American fliers, the Signal Corps has shipped to France 11,000 tons of various materials and has sent 7,000 mechanics to release for French factories making planes for our American fliers the French workers on motor transports. The Signal Corps then arranged for the making of about 11,500 combat planes in the United States, the term combat plane being here used to embrace all kinds of planes, both offensive and defensive, except training planes. The Curtiss Aeroplane Corporation, the Dayton Wright Aeroplane Company, the Fisher Body Company, the Standard Aero Corporation, the Grand Rapids Aeroplane Company, W. H. Mullen & Co., and about nineteen other companies throughout the country were engaged for the production either of completed machines or of spare parts.

"Let it be said here that when the war began the United

States Government had purchased altogether less than 200 aeroplanes in its entire history, and that of the few aeroplanes factories in this country probably not one was making over five or six a month. It is hardly possible to grasp the magnitude of the task the factories contracting to make the 71,500 combat planes found before them. New plants had to be constructed, old ones fundamentally changed. Special tools for the making of the planes had to be devised and manufactured, and mechanics had to be trained to make the tools and also to make the planes after the tools had been completed. An aeroplane, especially the battle aeroplane, is one of the most highly technical, delicate, and complicated machines known to man. In no other form of machinery is absolute and painstaking accuracy in the smallest details more indispensable. It has about 4,000 parts, and requires from 1,800 to 2,800 different drawings in the preparation for its manufacture—almost as many drawings as are required for a battleship. Every part is strained to the utmost while the machine is in the air, and the slightest break almost anywhere means instant disaster.

Perfection Necessary to Safety

"When it is remembered how often the wheels of railway trains, due to hot boxes, etc., parts of railway and automobile engines, tires on automobiles, etc., go wrong, necessitating immediate repair, and that any similar breakdown in an aeroplane would mean, as a rule, death to its occupants, some part of the responsibility and difficulty involved in making a finished plane may be understood.

"Remember further that every fighting plane must have machine guns, synchronizing devices, special telescope aeroplane sights, wireless apparatus, cameras of special type, electric heating devices for clothing, oxygen apparatus, speed indicators, special gauges, barometers, compasses, altometers, etc. To say that this complicated equipment is in steady and adequate production, and that the factories are now about in shape for quantity production of combat planes, and have about completed the foundation for what is as difficult and responsible a task as has ever fallen to the hand and brain of man, is to state the truth and at the same time to recite an achievement unparalleled in all history for so short a time.

"Remember again that when these combat planes were contracted for the only known lubricating oil adapted to their delicate parts was an oil made from the castor bean. There were not enough beans in this country to make anywhere near the amount of oil required. Neither were there enough seeds with which to grow the needed quantity of beans. The Signal Corps had to search the globe for seeds, and finally secured a shipload from distant India. Then the corps had to contract for the planting of the seeds in this country, and has succeeded in having about 110,000 acres planted. It is now claimed that a form of petroleum has been developed that will answer the same purpose. This, however, is still in the experimental stage, while the oil from the castor bean is known to be entirely adequate and reliable.

"Remember again that the cloth used in the wings of the aeroplanes of all types had to be treated with acetone, a liquid substance which makes the cloth as fireproof as possible, and also strengthens it for the immense strain to which it is subjected in the air. The Signal Corps is having this acetone distilled from wood under its own supervision on an enormous scale, and at a cost of about $20,000,000.

"The corps has had to find a substitute for Irish linen, as the material for wing cloths on training planes, and has succeeded in adapting a certain form of long staple cotton to this need.

"Coming to the training plane, it may well be said that the completion of 3,500 to date and the fact that they are now on quantity production, practically according to program, constitute a remarkable achievement when the nature of the task is fairly weighed. The training plane is simpler than the battle plane, and for that reason could be produced sooner, but the making of the training planes on a quantity scale is in itself a task of unprecedented difficulty and magnitude.

"Let it be remembered further that the Signal Corps had to put regiments of workers in the forests to find the spruce needed in the making of aeroplanes. The spruce trees are found among fir and other trees, and of each 100 feet cut only about 15 per cent is found good enough for aeroplane construction. Approximately 1,000,000,000 feet of lumber had to be cut and inspected and tested before the necessary 100,000,000 feet of spruce could be obtained.

"Propellers are made from mahogany and other highly durable woods, and three or four must be made for each machine. This mahogany comes from the tropics, and whether and when it can be brought to seaport depends on tropical rains, which swell the rivers so as to permit transportation.

Defends Liberty Motor

"Let us now consider the Liberty motor. The Liberty motor could not fairly have been called an experimental and untried device. It represented a combination of what had been demonstrated to be best in all motor construction. The Signal Corps, with its trained and skilled engineers, understood that a foreign motor could not be adapted to American manufacture and turned out in sufficient quantity in anywhere near the time in which the Liberty motor could be produced. Foreign motors are based on the metric system of measurements, etc. American practice and American manufacture are not adapted to this system. All parts made under the metric system must be converted into inches and fractions of inches under our system. The foreign motor is so extensively the result of hand work that it is with great difficulty adapted to the machine work that dominates American factories.

"Furthermore, the Liberty motor is capable of one hundred more horsepower than any foreign motor except a few of one single type, the Rolls-Royce. The Liberty motor develops 400-horsepower ordinarily and is capable of 465. The foreign limit, with the one exception above mentioned, is 300.

"The Liberty motor has become so well established that the British Government has asked for a large number. Sir William Weir, head of British aircraft production, stated recently in London that he considered the Liberty engine the greatest single factor in the world's aviation program; that it was the most important single thing in the air program of England in 1918.

"As soon as the Liberty motor had been designed, arrangements were made for the manufacture of a very large number before the close of 1918. The exact figures are withheld for military reasons. Henry Ford agreed to produce a substantial number of the total, the Packard another portion, the Lincoln Motor Company, Nordyke & Marmon, General Motors, and the Trego Company still another portion. These companies were notified to get ready last summer and the actual contracts were signed later. They have spent the intervening time preparing plants, tools, and workmen for this unprecedented work and are now on the eve of quantity production. The very names of those manufacturers are sufficient assurance that they would not take a day longer than necessary to lay proper and efficient foundations.

"The foreign planes which were accepted by the Signal Corps, known as light battle planes or single seaters, for which the Liberty motor is too heavy in horsepower, were none of those offered by foreign concerns that came to America soon after the war began to sell their wares, except the Handley-Page, and that was not the plane which the Handley-Page people first offered our Government on this side. Indeed, when the Handley-Page plane was first offered here it was untried and undeveloped, and had not been accepted by the British Government. The Signal Corps sent a commission abroad to study foreign planes on the ground, and accepted certain ones only after careful and personal study.

"On the whole the record of the Signal Corps is one of which every American can be justly proud. In the face of unparalleled difficulty it is accomplishing an unparalleled task with characteristic American energy, capacity, patriotism and enthusiasm."

The Vote in the Senate Committee

The majority report was signed by Senators Chamberlain, Chairman of the committee; Hitchcock, Reed, and Thomas, Democrats, and Weeks, Wadsworth, New, Frelinghuysen, and Sutherland, Republicans.

Senators Sheppard of Texas, Myers of Montana, and Kirby of Arkansas, all Democrats, put in the minority report defending the Administration and insisting that it has faced extraordinary difficulties that were not easily overcome.

Senators Fletcher, McKellar, and Beckman signed neither report.

W. A. MORGAN, LATE VICE-PRESIDENT OF THE CURTISS COMPANY, TELLS OF CONDITIONS THAT CAUSED AIRCRAFT PRODUCTION DELAY

IN a special interview with a representative of the New York *World*, Mr. W. A. Morgan, late vice-president of the Curtiss Aeroplane and Motor Corporation, discussed the conditions causing delays in production as follows:

"I joined the Curtiss Company on July 16 last. After sizing up the possibilities of the concern and talking to its staff of experts we went to Washington and consulted with the Aircraft Board as to the number of aeroplanes we could turn out. We figured conservatively that we could produce 3,000 pursuit 'planes and 1,000 bombers, from January 1 to July 1, 1918. The members of the Board said that if the $640,000,000 appropriation for our air service went through, they would give us a contract for that number of machines.

"At that time, understand, the appropriation had not yet gone through. But, relying on the word of the Board, we hurried back to Buffalo where I had taken an option on a piece of land and closed for it. The land and the necessary buildings for the work we purposed to do cost about $5,500,000. The Curtiss Company was not in a position to swing such a big deal and so I personally went out and borrowed $4,000,000 from a banking house. We got busy and began putting our buildings up within a few days. We had to send to Canada for some of the steel—but we got it into the country cheaper than we could have bought it here.

"Erection work was begun on July 27, and by September 15 we had 540,000 square feet of space inclosed. And up to this time we did not have the contract. I was staking everything on the word of the Aircraft Board.

Contract Signed, Then Cancelled

"The contract was signed on September 19. It was changed a little, so that it ordered 3,000 pursuit machines—fighting machines—and 500 heavier bombers. By November 2 we completed a second building and had a total of 1,170,000 square feet of space. We were ready to go ahead with our job—a $30,000,000 contract.

"But on November 7 last they cancelled the whole contract. This was because of the first of the many, many changes in design. The pursuit 'plane that we were to build was a copy of a certain French machine—a very good fighting 'plane which is still good enough to be in use in considerable numbers by the French. It was a single seater.

"But it seems that the Kaiser had sent some two-seaters over Verdun; that is, machines from which the pilot fired from the front and his companion had a second gun which he could fire at any 'plane which was chasing him. So the Aircraft Board immediately countermanded our order and set about to get a two-seater design. They accepted the Bristol, which is an English machine.

"We could have turned out the original 'plane ordered of us in great quantities very quickly. We could have begun production in December and got into quantity production in January, perhaps at the rate of 500 a month. We could have turned out any sort of 'plane they wanted, even the Bristol Fighter, at that rate, but we could not get the definite go ahead.

"My own belief is that it would have been far better to have made some of the original type; to have had 1,000 of them over there now protecting our lines, rather than to have none over there. We can't fight with designs. We have to fight with actual 'planes.

A Complete Halt

"Naturally, there was a complete halt when our contract was cancelled, but to make up for this cancellation the Board sent us word to go ahead and build 600 'planes of the 'advanced type.' This is a two-seated, dual-control machine which I may not describe in detail. But we showed them, with this ''plane,' what we could do in the way of production. We had a sample finished and in the air within ten days, and I believe the 600 have all been turned out and shipped by now.

"Finally we got our order for the Bristol Fighters. The contract was for 2,000.

"From the very beginning we were never able to get a definite 'go-ahead' order, so we could rush the production of this machine. We were, it must be remembered, maintaining immense overhead expenses. I personally was morally responsible for a $4,000,000 loan. Not that I cared so much about that. I'd give every cent I have to be able to feel that we'd turned out a great quantity of machines, that they were protecting our fighters, and that I had aided in doing this, as my contribution toward winning the war.

"Well, on November 28 the Executive Committee of the Curtiss Company wrote a strong letter to the Aircraft Board and told them that we were not responsible for any delays there had been, and that on account of these delays, which were not our fault, we felt that the Government should finance our operations—at least those extensions which we had made. This they agreed to do, and in January they took up our $4,000,000 mortgage.

Hundreds of Changes

"The changes that the Board ordered in the Bristol Fighter were literally hundreds. Their first great difficulty was about a motor. They decided primarily to use the Liberty eight-cylinder (which, as is now known, has been entirely discarded); but they found that would not fit in the Bristol. Then they decided upon a certain type of French motor, and then upon another type of French motor of greater power.

"These changes, of course, caused important changes in the machine, its balance and so on. Then they could not seem definitely to decide upon what sort of machine gun to use. They would order one kind, then another, then revert to the first again.

"This necessitated alterations in the machine proper and alterations in the gun mounts. Then a certain sort of instrument would be ordered and abandoned and another type ordered and abandoned. We never knew where we were—and here was a force of 11,000 men literally straining at the leash, ready to give all their strength and skill to the job of fast production."

"Any idea that reached here from abroad was seized by those in charge of our air programme," Mr. Morgan said. "It was a case of constantly copying something. In our air programme, I have found, no encouragement is given to American companies and American designers to produce something of their own.

"I do not want to appear to be holding a brief for the Curtiss Company alone. I know that all the others have had the same experience. But I do want to stick up for the American manufacturer in general, and I want to assert that we Americans can—and will if we are permitted—turn out as good aeroplanes as Germany does, and a great many more than Germany can turn out. We can produce enough to blind the Kaiser's armies if the authorities will let us go ahead.

No Trick to Do It

"It is no trick to turn out aeroplanes by the thousands—and I believe they will win the war—if the authorities will only decide what they want. But they hadn't the last I heard."

"What is the remedy for the situation?" Mr. Morgan was asked.

"Stop tinkering and let the manufacturers alone!" he replied. "As Mr. McNab of the President's Investigating Committee was quoted as saying the other day, if the authorities want to tinker let them get a big tract of land down in Virginia and tinker to their heart's content. Meanwhile the manufacturers will be producing."

MILITARY AEROSTATICS

HOW KITE BALLOONS DIRECT ARTILLERY FIRE

A CORRESPONDENT of the Associated Press, writing from "behind the British lines in France," describes his experience in a kite balloon observing artillery fire as follows:

"Would you care to go up?" asked the polite British officer in charge of the big kite balloon, one of the long line of captive sausages, the "eyes of the army," which swing as though pendant from the clouds all up and down the fighting line from the British channel to the Swiss border.

"Certainly," replied the correspondent, and so an extra warm overcoat and muffler were brought out and donned and, most important of all, the parachute harness was fitted on.

By this time the balloon had been connected up to the winch and everything was ready. The officer hoisted himself into the car with an agility born of long practice, while the visitor was assisted to his place by the "car men," who then hooked the harness to the parachute which hung just outside the little wicker car.

The Balloon's Equipment

Jutting out from one side of the car was a board on which was pasted a large-scale trench map of the district. In pockets inside the car were maps, air photographs and field glasses. On the rigging of the car was a dial to show the altitude and an indicator registering the force of the wind in miles per hour.

Just above, dominating all, was the huge bag of floating fabric, only kept in place by the crowd of soldiers holding the handling guys. The slender cable and its sister telephone wires stretched lazily across the grass to the winch on a big motor lorry nearby.

The observer fixed the telephone receiver to his head. He tested the line by calling up the winch party, the exchange and the chart room at the balloon section headquarters. Satisfied that all was ship-shape, he waved his arm to the flight-sergeant on the ground, who ordered crisply, "Let up hand over hand," and then, "Walk toward the winch."

Felt Shaky At First

The ground began to sink away. The first impression was that the bottom of the basket was going to fall out. For a few moments this impression was so strong that it was physically impossible to look over the side. The view was excellent, but the mood to appreciate it was absent. The officer's enthusiasm, as he pointed out different objects of interest in the landscapes, seemed somehow overdone.

Gradually this first impression of insecurity passed. The altitude dial, comfortably close at hand, now indicated that the balloon had reached 2,800 feet. The thermometer already showed a drop of twenty degrees. But the balloon was still rising.

"There is a light ground mist," explained the officer, "and experience proves that under such circumstances better results are obtained from higher altitudes." So it was not until the pointer signified 4,200 feet that he telephoned down the order, "Stop the winch," and the business of the day began.

Guided Battery Below

Artillery observation was the officer's appointed task. A British battery was going to "take on" a German battery, and the observer made his preparations accordingly. He had the positions of the two batteries marked on his map, but he wanted to make sure of the position of the balloon. So he leaned out over the side of the car, verified his landmarks and telephoned the results to the chart room.

"Let me know when they are ready," said he. There was a pause. Then a short monosyllabic conversation and the balloon officer gave the order, "Fire!" and adjusted his glasses to his eyes.

For the next fifteen minutes the officer was too busy to pay any attention to his passenger. He was engaged in "ranging," but from time to time he passed down a remark which showed that he was not confining his attention to ranging guns, but had also an alert eye for flashes of enemy guns anywhere within his range of observation. The range of vision was roughly twenty miles.

Phones Down Correction

After the first order to "Fire," a boom in the distance indicated that the order had been obeyed. The balloon officer frowned slightly, and telephoned a correction. A moment later the battery announced again that it was ready, and this time result was better. The process continued.

Once the observer asked to be put into direct communication with the battery, and the exchange arranged accordingly. Apparently the result of this conference was satisfactory, for soon the observation came through as correct.

A few more rounds and the balloon requested the battery to start firing for effect. While this

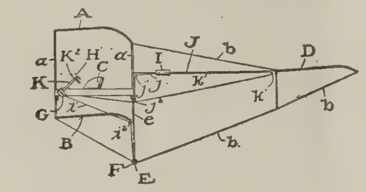
RECENT AERO PATENTS

BY WILLIAM N. MOORE

1,258,279. AEROPLANE. Frederick J. Veitch, New York, N. Y. Filed April 15, 1912. Serial No. 690,686. (Cl. 244—29.)

An aerocraft embodying a plurality of feight-carrying planes, a balancing plane in the rear of said weight-carrying planes, said balancing plane occupying an immovable position with reference to said weight-carrying planes, a lateral stabilizing and steering weight supported below the lower of said weight-carrying planes, means for controlling and adjusting the position of said weight with relation to said weight-carrying planes, a stabilizing vertical steering weight supported for movement between the weight-carrying planes and the balancing plane, and controlling means for shifting and retaining in position said vertical steering weight.



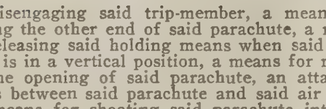
An aerocraft having independent slidable weights for steering the same in horizontal and vertical directions, in combination with two operating spindles one of which is tubular and incases the other, hand wheels on said spindles, and operative connections between the spindles and said movable weights.

An aerocraft having movable weights for steering the same in horizontal and vertical directions, in combination with two operating spindles one of which is tubular and incases the other, hand wheels on said spindles, and operative connections between the spindles and said movable weights.

An aerocraft having movable weights for steering the same in horizontal and vertical directions, in combination with two operating spindles one of which is tubular and incases the other, hand wheels on said spindles, and running cords operated by the spindles and connected to said weights.

1,258,356. AERIAL MACHINE. Albert W. Myers and Robert R. Fitz Gerald, Ottawa, Ontario, Canada, assignors to Albert W. Myers, Ottawa, Ontario, Canada. Filed August 29, 1917. Serial No. 188,853. (Cl. 244—21.)

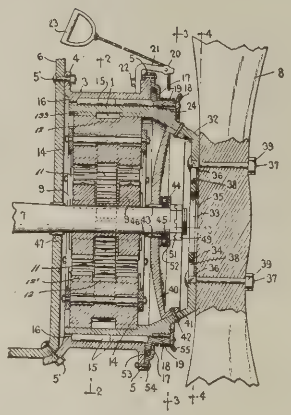
A safety attachment for aerial machines consisting of a parachute, a trip-member adapted to engage at the free end of the parachute, means for disengaging said trip-member, a means for holding the other end of said parachute, a means for releasing said holding means when said parachute is in a vertical position, a means for releasing the opening of said parachute, an attaching means between said parachute and said air craft, and means for shooting said parachute into the air.



1,258,450. AEROPLANE-STARTER. Merrill Pepperd, Wilmore, Kans. Filed September 5, 1917. Serial No. 189,826. (Cl. 74—54.)

In a starter of the class described, the combination of a stationary cylindrical housing, supporting means for said housing, a rotatable drum journaled within said housing, a centrally arranged shaft, an internal gear face within said drum, a train of gears interposed between said internal gear face and said centrally arranged shaft for accelerating the rotation of the shaft in relation to said drum, an oscillatory rim surrounding a portion of said drum, pawl and ratchet means between said rim and drum, and a flexible operating cable surrounding said oscillatory rim and attached thereto.

In a starter of the class described, the combination of a stationary cylindrical housing, supporting means for said housing, a rotatable drum journaled within said housing, a centrally arranged shaft, an internal gear face within said drum, a train of gears interposed between said internal gear face and said centrally arranged shaft for accelerating the rotation of the shaft in relation to said drum, an oscillatory rim surrounding a portion of said drum, pawl and ratchet means between said rim and drum, a flexible operating cable surrounding said oscillatory rim and attached thereto, and a return spring for actuating said drum in the opposite direction.

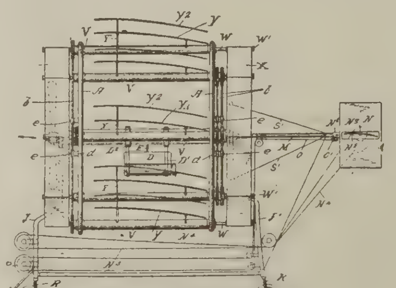


In a starter of the class described, the combination of a stationary cylindrical housing, supporting means for said housing, a rotatamle drum journaled within said housing, a centrally arranged shaft, an internal gear face within said drum, a train of gears interposed between said internal gear face and said centrally arranged shaft for accelerating the rotation of the shaft in relation to said drum, an oscillatory rim surrounding a portion of said drum, pawl and ratchet means between said rim and drum, a flexible operating cable surrounding said oscillatory rim and attached thereto, said pawl and ratchet means comprising a ratchet face on the drum, a pawl adapted to co-operate therewith and pivotally carried by said oscillatory rim, yieldable means normally holding said pawl out of engagement, and means operated upon by said cable serving to press the pawl into engagement with the ratchet face.

In a starter of the class described, the combination of a stationary cylindrical housing, supporting means for said housing, a rotatable drum journaled within said housing, a centrally arranged shaft, an internal gear face within said drum, a train of gears interposed between said internal gear face and said centrally arranged shaft for accelerating the rotation of the shaft in relation to said drum, an oscillatory rim surrounding a portion of said drum, pawl and ratchet means between said rim and drum, a flexible operating cable surrounding said oscillatory rim and attached thereto, said pawl and ratchet means comprising a ratchet face of the drum, a pawl adapted to co-operate therewith and pivotally carried by said oscillatory rim, yieldable means normally holding said pawl out of engagement, and means operated upon by said cable serving to press the pawl into engagement with the ratchet face, said yieldable means also serving to press the last named means outwardly to permit the pawl to move out of engagement with the ratchet face.

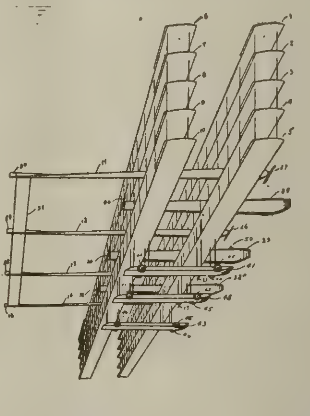
1,258,943. FLYING-MACHINE. Edmund Hugh Pryce, New York, N. Y. Filed December 15, 1911, Serial No. 665,906. Renewed July 30, 1917. Serial No. 183,638. (Cl. 244—14.)

In a flying machine, a central relatively stationary element, a frame mounted on said element and rotatable relative thereto, shafts carried by said frame and rotatable therein, supporting planes carried by said shafts to sustain the machine by the sustaining action of the air exerted through the rapid forward motion of the machine, means for automatically controlling the rotation of said shafts through the rotation of the frame relatively to the stationary element to maintain the planes in proper position to sustain the machine, and means for propelling said machine.



1,259,083. AEROPLANE. Isaac Covino, West New York, N. J. Filed October 25, 1917. Serial No. 198,529. (Cl. 244—14.)

An aeroplane of the multiplane type, having two sets of multiplanes, a tractor system of propulsion composed of four propellers and their respective motive powers located each on a separate body; said bodies being far apart so that equilibrium is maintained when flying; an after system of propulsion composed of three propellers with their respective motive powers all located at the rear end of the larger bodies, a horizontal rudder located at the rear end of the four tractor bodies, four vertical rudders located at the end of each of the four tractor bodies; landing wheels to allow aeroplane to move on land and pontoons to allow aeroplane to float and move on the surface of the water, all substantially as described.



(*Continued from page 263*)

was being done, another battery was rung up and ranging done on another target, the balloon observer occasionally switching his glasses to the old target to see that the guns were shooting correctly.

Now and again the observer passed down a message to the effect that "Blank-Blank is active." Blank-Blank was another hostile battery, not at present engaging attention. Sometimes he interpolated a little message for the chart room such as:

"Flash observed two five minutes left of Blank-Blank," Blank-Blank being a landmark easily found on the map, so that the flash position could be marked on the chartroom for attention later.

Results of the Work

There were four hours of this work before the officer gave the order, "Haul down." A slight jerk showed that the descent had begun, and fifteen minutes later terra firma was reached and the balloon was off upward again with a fresh crew.

Down in the chartroom the report of the day's work so far showed that three German batteries had been "neutralized" and two new battery positions discovered. In due course, the latter two would be cared for in a manner that would place them also on the list of neutralizations.

Not every balloon ascent is so smooth and peaceful as this. The enemy is active and ingenious, and the parachute is not there for nothing. The German airman, swooping like a hawk from a cloud, is always a possibility.

FOREIGN NEWS

AUSTRIA

The Cologne *Gazette* says that an aerial mail service is being established between Vienna and Kiev and also between Odessa and Constantinople.

CANADA

A Canadian *Daily Record* telegram reports that the first 1,000 aeroplane engines which are being built in Toronto, have been completed and tested. The engines are being constructed at a plant worked by the Imperial Munitions Board.

FRANCE

The French official statement for April 1st, reports intense aerial activity and the destruction of enemy aeroplanes, as follows:

"On March 29-30 our aviators, despite rain and mist, carried out numerous sorties. Five thousand kilograms of explosives were dropped on enemy cantonments and stations in the region of St. Quentin, Guiscard and Roye. Our aeroplanes frequently attacked with machine gun and bombs enemy concentrations, which they dispersed. Nine German aeroplanes and one captive balloon were destroyed by our pilots.

"Italian bombing machines took an active part in these expeditions, and recently carried out with splendid audacity numerous raids on the enemy lines."

The War Office issued a statement on aerial activity on April 3rd, as follows:

"On March 31 and April 1 French aerial squadrons threw down 12,000 kilograms (more than thirteen tons) of projectiles on railways and cantonments at Ham, Chauny, Noyon, etc. A large fire was observed in the railway station at Onauines. German cantonments in the region of Roye were bombarded with many projectiles and attacked with machine guns from a low elevation. French pursuit planes were engaged in many fights, in the course of which eight German aeroplanes were brought down. Two others were put out of action."

The announcement of April 7th reports French aerial successes:

"On April 6 seven German aeroplanes and two captive balloons were brought down by our pilots. Our bombers dropped 5,000 kilos of projectiles on enemy stations and cantonments.

Enemy airmen unsuccessfully attempted an early morning bombardment of Paris on April 2nd. An official communication says:

"Two flotillas of German aeroplanes crossed the lines flying toward Paris early this morning. They did not penetrate the Paris barrage defense, but made a half turn, dropping bombs in the suburbs. There were no casualties."

The official reports of aerial activity during Germany's great effort to break the Allied lines are very brief, but an indication of the magnitude of these operations can be gleaned from a United Press dispatch, which states that an Allied squadron of eighty machines pursued a German squadron of forty.

In the recent German aerial attack on Paris, one of the enemy aviators dropped a bomb which struck and damaged the embassy building of one of the Central Powers.

Two days later the caretaker of the building requested the legation of the neutral power representing the enemy's country to present a bill to the French Government for the damages done to the building.

France is asked to pay $900 for the destruction by the enemy of his own property.

Second Lieutenant Prince de Tonnay-Charente, one of the most promising young French aviators, is missing. He has brought down seven German machines.

GERMANY

Germany's aerial activity during the great offensive does not appear from the official announcements to be increasing in intensity. The official announcement of April 2nd, says:

"Twenty-two enemy aeroplanes and five captive balloons were brought down. Lieut. Kroll won his twenty-third aerial victory. By the energetic carrying out of long-distance observation from the coast as far as south of the Somme, aerial detachment No. 3, under Lieut. Friecke, rendered extraordinary service."

"Cavalry Captain Baron von Richthofen won his seventy-fifth aerial combat," says the German official announcement of April 3rd.

The War Office announced on April 7th that:

"In aerial battles eighteen enemy aeroplanes were shot down yesterday."

Dispatches to Les Nouvelles state that on the occasion of the last Allied air raid on Coblenz, twenty-six persons were killed and one hundred wounded. Great damage was done, the railroad station being demolished. In the last raid on Treves sixty were killed and hundreds were wounded, the railroad station was damaged and streets in the neighborhood were heaped with ruins.

In the raid last week the Cologne station was hit and many buildings were demolished. A troop train standing in the station was struck and many occupants were killed or wounded. The Emperor visited the spot the following day. A later dispatch from Geneva states that the recent British aerial raids on Cologne caused 248 deaths, half of whom were soldiers, according to the latest reports received at Basel. The soldiers were in a railway train bound for the Picardy front and standing at the Cologne station. Panic reigned in the city for twelve hours, the streets were deserted and the population hid in cellars. One report says that a Major was killed.

Emperor William was conferred upon Baron von Richthofen, the German aviator, the Order of the Red Eagle, with crown and swords.

GREAT BRITAIN

The British official statement for April 2nd reports aerial activity on the part of contact patrol and bombing squadrons, as follows:

"There was good visibility Monday and our low flying aeroplanes again were active. More than seventeen tons of bombs were dropped and thousands of rounds were fired from the air at the enemy's infantry and other targets on the ground. Hostile aircraft also were active on the southern portion of our front, some of their two-seated machines firing at our troops with machine guns from low heights.

"Ten hostile aeroplanes were destroyed and six others driven down out of control. Another aeroplane was brought down within our lines by infantry. Two hostile balloons were destroyed by our aeroplanes. Eleven of our machines are missing.

"After dark our night flying machines bombed enemy railway stations, billets, troops and transport, dropping many bombs on the Cambrai railway station, on the station southeast of Douai, on the railway lines south of that town, as well as on other targets. All of our machines returned."

The announcement issued April 3rd reports the following aerial activity:

"Hostile troops and transport on roads again were harassed Tuesday with bombs and machine gun fire. Over a thousand bombs were dropped during the day.

"The enemy's aeroplanes were fairly active between Albert and Moreuil. Thirteen German machines were brought down, eight were driven down out of control and three hostile balloons were destroyed. Seven of our machines are missing.

"At night rain fell continuously until 3 o'clock in the morning, after which time four and one-half tons of bombs were dropped on hostile billets and troops.

"Yesterday our aviators dropped seventeen tons of bombs and brought down sixteen German aeroplanes."

The official statement on aviation issued by the War Office April 4th says:

"Wednesday again was unfavorable for flying, but this did not prevent our aeroplanes from making several flights to reconnoiter the battle front and attack ground targets with bombs and machine guns. One fight occurred during a clear interval between two very large formations of our own and enemy machines. Otherwise hostile aircraft were not very active.

"Nine German machines were shot down, three were driven down out of control and one hostile balloon was destroyed. Five of our aeroplanes are missing."

The announcement of April 7th reports operations by large aerial units, as follows:

"About noon on Saturday our machines, watching the enemy's movements on the battlefront reported a concentration of hostile troops south of the Somme. Large formations of our aeroplanes issued immediately in the rain and dropped more than five hundred bombs on the enemy's assembled infantry, in addition to firing some 50,000 rounds at them with machine guns.

"In air fighting thirteen hostile machines were brought down and eleven others disabled. Two German machines also were shot down by anti-aircraft guns. Sixteen of our machines have not yet been located. Many of these undoubtedly made forced landings behind our lines, owing to the difficulty of finding their aerodromes in the heavy rain.

"Throughout the present battle the Canadian air force has done valuable work."

The British War office pays a high compliment to American airmen in the official statement issued April 3rd on aerial operations, which says:

"During the last fortnight of intense fighting in the air, the assistance rendered by the personnel of the American air service attached to the Royal air service has been invaluable."

A New York *Times* cable dispatch summarizes aerial activity during the great offensive, as follows:

"During the period from March 20-21 down to April 3-4, the British brought down at the front 240 German aeroplanes and drove down 123 out of control. During the same period the British had 122 machines missing.

"Excluding the bombs dropped in raids on Germany, British aircraft dropped during the same period 179¼ tons of bombs by day and 151 tons by night, a total of 300¼ tons. They also in the same period fired 1,139,525 rounds of ammunition from machine guns upon ground targets.

"When it is remembered that in order to fire upon ground targets the aeroplane has to take a special dive and in each dive fires only ten or twelve rounds perhaps, some idea can be formed of the enormous amount of work represented by these fighters. The maximum number of rounds fired at ground targets in a single day was 250,000, and in a single night 63,000. The maximum weight of bombs dropped during a single day was 31 tons, and in a single night 27¾ tons.

"In a single day one British brigade captured twenty-two German aeroplanes and drove down seven.

"Last month's long-distance bombing raids comprised thirteen British raids on German towns and only one German raid upon London."

How necessary the rapid building of aeroplanes is, can be gathered from the official reports of losses on all battle fronts during February, as reported by Associated Press correspondence. These totalled 361, of which 268 fell on the western front, eighty-five in Italy, four in Palestine, three in Macedonia and one in Mesopotamia.

The Allies report that 273 German and Austrian machines were brought to earth by Entente airmen, while the German Headquarters claim to have brought down eighty-eight Allied machines on the various fronts.

Losses for December on the western and Italian fronts alone were 390.

ITALY

American aviators are engaged in signal work on the Austrian front (in Italy), according to a despatch to the *Intransigeant,* of Zurich.

LARGE scale models are rather uncommon among the average builders and we believe our readers will be interested in the six-foot scale model which is described by its constructor, Private Eugene J. McGuirk, Jr., a motor repair man in the Aviation Section, Signal Corps, U. S. Army. Mr. McGuirk's connection with the aviation division makes the model the more interesting, being so closely in touch with the full-sized aeroplanes of Uncle Sam's training stations. After being stationed at Kelly Field and Love Field Mr. McGuirk was transferred to the 196th Aero Squadron at Lake Charles, La.; from there he hopes to go "over the pond."

Specifications of the materials and construction of the McGuirk scout model are as follows:

Fuselage constructed of 3/16" square longerons and distance pieces of the same material. The curved fuselage top (or "turtle back") is built of cypress formers upon which is laid 3/16" by 1/32" spruce battens.

In the forward portion the fuselage is covered with sheet aluminum and the rear part with linen, which is doped and varnished after the manner of the large aeroplanes.

The pilot's cockpit is upholstered with leather and provided with a miniature aluminum seat.

All the controls are made to operate the controlling surfaces in the usual manner. Deep control is used—a wheel connected to the ailerons, the control column operating the tail-flaps or elevators, and a foot-bar for the directional rudder. The ailerons are hinged on auxiliary wing beams 1½ inches to the rear of main wing beam. This allows a slot to be cut into the main wing for the operation of the control lever.

From tip to tip, the main wings measure 72". The chord is 12" and the gap 13". Wing spars and entering and trailing edges are of spruce. Ribs are of the block-and-batten type, built up of very thin strips of spruce which are spaced by means of small blocks to form the proper wing curve; four such blocks being used in each rib. Rib spacing 1½" apart.

E. J. McGuirk's 6-foot scale model Scout.

Covering is with silk which is given three coats of varnish.

Wiring between the planes is similar to that employed on the famous French "Spad"; the wires cross at the center struts. Strut fittings are cut from sheet aluminum and turnbuckles are made of bicycle spokes and nipples.

In the landing gear, each wheel is made of two cupped discs of aluminum which are held together by a copper-tube hub, the ends of which are riveted to hold the halves of the wheel together. The tires are made of raw gum rubber. The axle is bound to the chassis with elastic, for the shock absorbing effect.

At the forward end of the fuselage, a dummy six-cylinder motor is set so that the tops of the cylinders project through the cowling. The motor is carved from a block of wood, the cylinders painted black to resemble cast iron.

Correspondence Model Club News

Edwin A. Jenkins, Mem. Secretary of the Corrsependence Model Aero Club, wishes to make public the fact that the Club is now preparing a "Spring Drive" for new members. The example of this organization might well be followed by other model clubs in an effort to stimulate increased interest in the science. Progressiveness is evidenced in the Correspondence Model Aero Club's continued activity, and all interested are urged to participate with it in the good work.

A bulletin is published by the Club, which is supplied without charge to members. Those who write to the Secretary, Edwin A. Jenkins, 1141 Bushwick Ave., Brooklyn, N. Y., will receive a sample copy of the Club bulletin together with full particulars about membership.

Scale models of Halberstadt Scout with a 30 inch spread and a Wright Flying Boat with a 36 inch spread. These models, built by Jacob Dunnell and W. B. Lane, were described in Aerial Age last week.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Some Rules for the Guidance of Hull Draughtsmen and Boat Builders

To Draughtsmen.

In getting out drawings for use of the Boat Shop it is advisable to make full size drawings as it makes easier work for the man to walk about on them to have a look at what they are supposed to build.

When laying off lines on the floor it is as well to use a good lump of chalk off the beach, broken up into fairly small pieces, so that they get well scattered and trodden in.

It is suggested that as at present we have no proper floor, the laying off might be done on the beach on a good clear stretch of sand; the tides will probably wash it out, but our draughtsmen have not much to do and might manage to get through the work in a few months.

If in doubt about what you have shown on any tracing ask one of the Hull Inspectors or Air Board D.O. what it really is; they are certain to be able to solve these little problems, if they cannot they will let you know in a month or two, or drop the matter altogether.

To Boat Builders.

This trade is a very simple one, although people are foolish enough to serve an apprenticeship to qualify; anyone with a small kit of tools and no common sense can work at it and produce a complete flying boat hull in a few days. (See our paper patterns.)

If you have not done any work of this sort before, and you have to buy tools, it is advisable to purchase heavy hammers, spanners, and cold chisels, etc., the work is light, but heavy tools last longer.

Never drill holes for driving copper nails into hard wood, the nails will drive quite easily; only drill holes rather larger than the nails to be used in soft wood, they can then be pushed in with the thumb more easily.

Rose burrs are only for decorative purposes, as long as they just hang on and are well driven into the wood they look all right.

The slots in screws are only meant for taking them out with; screws can always be driven in with a big hammer.

Planking joints need not be a good fit, as the two thicknesses of planking are only used to support the oiled calico in between.

Do not trouble to consult any drawings, these are only got out for the amusement of our Draughtsmen; it is as well to look occasionally at them as you would at a picture, it pleases the man who made them.

If you break a screw head off don't bother, glue in a dummy head so that it looks all right.

Put plenty of nails in planking, it does not matter if they are driven into anything else inside; they look nice and bright when the heads are filed off.

Colored putty and brown paper are good things.

Don't worry your Foreman or Charge Hand; they don't know any more about it than you do.

If you want any wood get it yourself. If it is cut into about six-inch lengths it is easy to split up for firewood.

When hulls are completed they should be sent to the Erecting Shop, where they will see that the varnish is well scratched up and the woodwork marked with heavily nailed boots. The fine finish is only put on the boats to keep the Boat Shop going.

Be accurate in your measurements in case the A. I. D. Inspectors level and plumb one of them up to see that one side is not more than three thirty-seconds of an inch wider than the other.

Always look out to be near the door when the whistle goes, the Canteen sprint gives you an appetite; it does not matter what time you start work again as long as you clock in.

"What dear little tires! How many miles do you get out of them?"

In the Future

She: "Say, porter, how long is this dark cloud we're coming to?"

Porter: "If youse couple am jes' married, about long enough for one, but if you hab been in that state for some time, ah should say long enough for about foah jabs on the jaw."—*Gargoyle.*

Evident

She: "That scar on your head must be very annoying."

Aviator: "Oh, it's next to nothing."—*Columbia Jester.*

Making Certain

Kernel: Did you bury all the dead as I ordered this morning?

Privit: Yes, sir, but we had a little trouble with one of them.

Kernel: What?

Privit: Why, one of them raised up on his elbow and said he wasn't dead, but then he was one of them d—d Germans, and you never can believe anything they say, so we buried him anyway.—*Awgwan.*

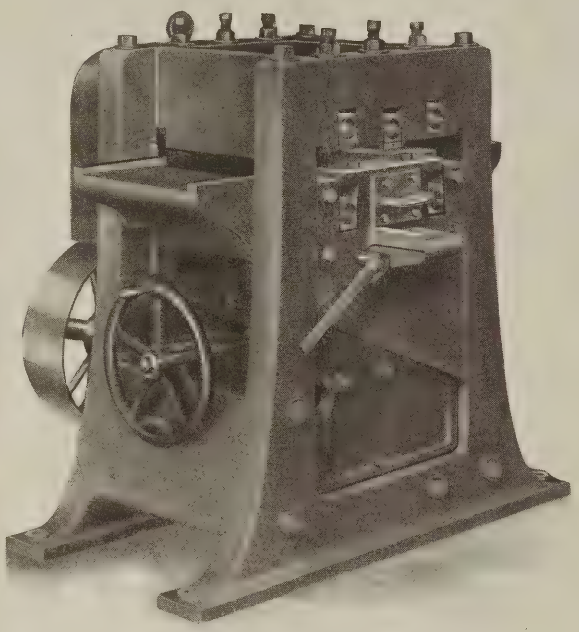
Not Yet

Alumnus of '78: "Who is that man over there with all the decorations? A French war hero?"

Fresh: "Naw, that's a guy that subscribed to the two Liberty loans, the Friendship Fund, the Army 'Y,' the Prison Camp Drive and the Red Cross Society."—*Gargoyle.*

Aeroplane Propeller Stock

Toothed at the rate of 100 feet per minute by running it through a



Whitney Scraping and Toothing Machine

WHITNEY

Toothing Machine

If you want to prepare your Propeller stock before gluing up by the quickest—easiest—safest and cheapest method, just put it through a Whitney Toothing Machine.

Many of the Aeroplane Manufacturers, as well as Propeller Makers, are using this machine.

It will pay you to investigate.

1 WALL STREET NEW YORK, N. Y.

WE SPECIALIZE

3 ply, 5 ply, 9 ply and 15 ply, birch, mahogany, walnut and red gum waterproof veneers. Our products have officially passed Government test of boiling of twenty-four hours and baking twenty-four hours. Capacity 30,000 square feet daily. In an official Government report on sample three and five ply panels submitted by us for test, it was stated—

> **"Boiling tests and salt water soaking tests as follows were made on each specimen: Specimens were boiled for 8 hours, then baked for 24 hours at 100 deg. C.; specimens were soaked in salt water (4% salt by weight) at room temperature for 24 hours and then baked for 24 hours at 100 deg. C.**
>
> **"Results:—The glue held firmly in all tests. Neither the boiling nor the salt water soaking tests caused any indications of separations of the plies of the veneers tested."**
>
> **Dated, March 30th, 1918.**

Laminated wing beams of spruce. We have under contract a supply of aeroplane spruce and could undertake to manufacture 50 sets of 8 wing-beams daily. In an official Government report on a sample wing-beam section submitted by us for test, it was stated —

> **"Conclusion:—These beams carried a much greater transverse load than solid wood beams of the same material and section. The glue joints between web and flanges are stronger in shear than the web section, and the glue had fairly good waterproof qualities. These beams show the superiority of the laminated construction over the solid construction as to strength and great saving in material."**
>
> **Dated, March 11th, 1918.**

We offer single ply birch, maple, walnut, mahogany and red gum in sizes cut to order.

SHIPPER IN CAR LOTS OF

Spruce, Ash, Oak, Birch, Cherry and other manufactured aeroplane lumber.

ALLIES MORE IN NEED OF PLANES THAN SOLDIERS

Major Gordon P. Howe, Back From Picardy Fighting, So Announces

"OF course, it is as an airman that I say this, and there is a shadow of a chance that I may be wrong. But it seems to me that we need aeroplanes from the United States even more than we need men. This, mark you, though the skies over the Picardy lines are so thick with them that one might almost say the sun is obscured."

Major Gordon P. Howe, of the British Flying Corps, offered this comment on the present European situation. He arrived at an American port on his way to Canada, invalided home after three and a half years at the war front. He has served a year each in infantry, cavalry and aviation corps and dropped to the ground from shell shock on the third day of the present German offensive. He is 29 years old.

"Whatever I may tell you about the conditions in air fighting up to the time I was brought down," said Major Howe, "is bound to be inadequate, even though I was there myself and saw. It must be incredible, I'm sure, to be told that the air over the fighting front is so sown with planes of every sort, and dirigibles, too, that driving one is as difficult as manœuvring a car down Fifth avenue on a crowded afternoon; but I am stating an actual fact.

"As many of our men have been brought down from collision as from gunfire. We have the ascendency over the Germans so far, and I hope it lasts. But we need more planes; as fast as you can turn them, and not by the hundreds, but by the thousands."

Air Scene Described

One of the first to reach this country with an actual participant's account of the present fighting conditions, Major Howe reiterated again and again that his description did the facts imperfect justice.

He said that when Von Hinderburg's great drive began the Germans threw out before and above their armies a fleet of scout and battleplanes so vast as to justify the inference that they must have considered it insuperable. It was met by an allied resistance in the air which even Major Howe, taking part in it, had not believed possible, and for the first forty-eight hours of the mighty conflict the air-fighters struggled for the mastery on fairly equal terms.

It was upon the third day that the defenders began very slowly to gain. It is the belief of Major Howe that they still hold the ascendancy, and he bases this on what he heard up to the day he left France and on his own observation that the German airmen in general lack the initiative and inventiveness of their opponents and that at times their organization seems inadequate to the task they undertake.

"It is singular that they should have gone short in the matter of organization. One has heard and still hears so very much of German organization and its infallibility. Still, by the third day, having started out more than equal with us, they were being shot down almost continuously and their reserve planes were not coming up.

Unable to Fill Gaps

"We had bombed a number of their hangars and munition depots, and of course they were on the offensive and their armies pressing steadily forward. Nevertheless they seemed unable to fill the gaps made in their air ranks. Possibly they had not expected to suffer so many gaps and had made no provision against them, or else they had not expected night fighting in the air, which we kept up unremittingly.

"In any event, while I was still in the fight, they were making frantic efforts to re-enforce their machines with machines from other sectors and for some reason, which I do not know, were not succeeding. They began sending up their smaller and medium dirigibles on the second day, and of course, with the fighting so thick in the air, these suffered instantly.

"You may imagine the character of the fighting when I explain that in the immediate neighborhood of the firing lines the difficulty was as much to get into the air as to stay there afterward without being hit. It was precisely like wedging one's car into heavy city traffic without the benefit of the traffic rules.

"Collisions were constant and as often fatal. There is no way of describing it and making the description convincing. The air was full of fighting craft of every manner and kind."

Major Howe had been in the air twelve hours without once coming down, when he was hit; and was a little out of the thickest of the fighting, having gone back over the German lines.

His Fight With Enemy

"I was attacked on two sides, or rather from before and above, when I was put out of it. There was a heavy fighting machine forward of me and I had gone in pursuit of it when it turned and came back to meet me. While we were both firing another German plane assailed me from above. Neither he nor the one ahead was able to hit my machine, but the man above finally let a bomb drop, which exploded right beside me.

"Although I was not hit by any part of the shell, the concussion rendered me unconscious, and when I regained my senses I was in a hospital. I have no idea how I got to the ground, but men who saw it all told me that I retained control of my machine until it was a few feet from the earth. I must have guided it subconsciously. Such things are not uncommon.

"I wish to add just this more. Even after all they have been through there is no fear in the minds of the allied fighting forces as to the final outcome either of the present battle or of the war. None whatever."

EDITORIAL COMMENT ON AIRCRAFT SITUATION

Aeroplane Mistakes

(Editorial in New York *Evening Post*)

The Senate Military Committee's findings against the Administration in the matter of aeroplane production fall under two general heads. There has been a failure to realize attainable efficiency, and this failure has been aggravated by official promises and reports altogether misleading in their excessive optimism. On the second count there is not much that can be said in rebuttal. From Secretary Baker down there has been altogether too much readiness to fall in with popular conceptions of an enormous aviation programme that could be realized by a *tour de force* of American inventive ingenuity and hustle. Mr. Baker has himself to blame for the natural reaction that has followed upon the circus flourish with which the "invention" of the Liberty motor was given to the world. Mr. Baker might have remembered that the man in the street would not stop to differentiate between training planes, flying planes, and battle-planes, when he was assured several months ago by Mr. Baker that the aeroplane programme had reached the stage of quantity production. It is somewhat too late for the minority report of the Senate Committee to emphasize the enormous complexities and minutiæ of aeroplane building—the necessity of planting great acreages in India for the growth of the oil-seed for motor lubrication, the establishment of factories for the production of aeroplane varnish, the importation of mahogany from the tropics. All these things should have been kept in mind by the war officials in their communications to the public.

Putting aside all unreasonable expectations raised by official loquacity, it is still true that in the realization of even a moderate programme there have been disappointments. There has been too much shuffling of plans. Presumably, this arose from the same desire for perfection which entered into the machine-gun situation, and which in the case of the Browning gun has been justified by the comparatively slight delay, and by the fact that there was concentration on a single technical problem. The advocates of the Browning gun knew exactly what they wanted. The aeroplane alterations and delays have arisen from an excessive experimentation in war-time. But beyond that we find evidence of an actual lack of co-ordination on the administrative side. We can understand why the War Department should have decided to manufacture its battle-planes in France and should have sent over a large force of American mechanics for the purpose, while concentrating production in this country on trial planes and fast machines. But in that case we should not have sent over to Europe 1,200 flying cadets, of whom the Senate Committee reports that only 450 have received their primary training for lack of planes, and the others may have to be brought back.

There is a fundamental consideration which underlies our aeroplane mobilization as it underlies our effort in the matter of men, guns, food, and raw materials. This principle is a simple one. It consists in formulating our plans in accordance with the advice and the desire of the Allies. The transfer of our troops to Allied leadership is only the most striking example of this programme of ready service. The Allies asked us to send men for whom they would supply the guns and equipment, and we have done so. The Allies asked for the shipment of raw material and labor in preference to the finished product as a means of saving time and tonnage, and we have complied. Take this question of battle-planes. On our failure to produce them the heaviest weight of criticism has fallen. Yet the hostile Senate Committee report states:

Arrangements have been made with France for the construction there of 6,000 battle-planes by 7,000 American mechanics sent across the ocean for the purpose and using 11,000 tons of American material.

Why was not this plan made known to the American public? The knowledge that American labor is occupied in building battle-planes out of American material in France would obviously have been the answer to the charge that up till now we have shipped just one battle-plane to France.

The situation, therefore, is one in which mistakes of administration have been greatly aggravated by unhappy publicity methods. The mistakes of management must be remedied, and doubtless will be remedied on the basis of the two Senate reports and the findings of the President's special committee. But it is essential, and it is not too late, to give the public a true idea of the problems involved in the execution of our aviation programme, and on the other hand to remove the unjustified apprehensions that have been created by the "breakdown" of that programme. It is not true, as partisan critics have tried to make us believe, that our men in France are facing the enemy without aeroplane protection. We have the use of the Allied battle-planes just as we have the use of Allied guns. We are not making rapid progress toward the ideal of 20,000 American planes that were to win the war, but that was always a counsel of perfection, and has been pushed into the background by immediate needs. A simple statement from authoritative quarters that we have had more need to think of men and food and shipping than of aeroplanes would have saved the Administration a large measure of unjustifiable criticism.

Our Delayed Aeroplanes

(Editorial in New York *Evening Sun*)

About as thorough in condemnation as any official opinion on the war preparations given out since the start is the report of the Senate Committee on Military Affairs, dealing with the record of the Signal Corps in regard to aircraft production. If good comes of the report's recommendations, the Signal Corps will be set back at its old work of making signals, and a single, absolute and forcible person will get the job of turning out aeroplanes as fast as he can, with something extra of speed to make up for lost time.

The man can be found. He will probably have to spend some busy days and nights learning, as to aeroplanes, a slight part of the technical lore that the Signal Corps could not forget. Aviation being new, we lack a community of practical aviation men, such as our communities of railroad men, steel men, mining men and banking men. The technical equipment of the man who is to translate our aircraft plans from paper to fact will count for less than his driving power. Let us have a man who knows what he is after, in a matter-of-fact even if not in an elaborate way; one who means to get it; one who can by dint of his faith and power in his own purpose move the mountains of subordinate indifference, cut the entanglements of organization red tape and force a thoroughfare through the conflicting claims of other activities.

The damage done by delay need not occupy our thoughts any longer. It would need discussion only if any one, outside of Mr. Creel, doubted the delay in aircraft construction. The minority report presents so cold and artificial a defence of the Signal Corps as to reveal quite pitilessly its signers' own adverse conviction in the face of their perfunctory make-believe. The Signal Corps is condemned.

Once we agree what is wrong, the need of the hour is the remedy. The Senate's committee, with its sweeping proposal, has found the right plan for supplying the lacking aircraft in the shortest time possible.

It will profit nobody if the report of the Senate Committee on Military Affairs about our failure to produce aeroplanes for war service is treated merely as a contribution to the files of the document room. The report reveals what the committee very temperately describes as a "gravely disappointing situation." We need not dwell upon the details of the conditions the committee found to exist. The disappointment to the country will not be softened by anything contained in the minority report signed by three Democratic members of the committee. They merely set up in palliation of the shortcomings in aeroplane production the very great difficulties encountered in the work. In time of war men must be found who can overcome difficulties.

The important thing now is to end the country's disappointment, to win success where the record thus far is largely one of failure. The facts are before Congress, before the Administration. The recommendation of the committee is that "the matter of production should be taken out of the hands of the Signal Corps entirely," that it "should be controlled by one executive officer appointed by the President and responsible to him." The recommendation and the report cannot be ignored. The matter is far too serious for any further exhibition of a "certain aloofness in dealing with persons possessing information based upon experience" to which the committee report refers as one of the causes of failure. Mistakes have been made, very serious mistakes, that cannot be denied. They should be frankly admitted and promptly corrected. That is the best way out of a pretty bad situation. That way will best satisfy the country, it is the best way to hasten the production of aeroplanes for use of American soldiers in France.

THE NEWS OF THE WEEK

Colonel Raynal C. Bolling Missing

Colonel Raynal C. Bolling, former general counsel for the United States Steel Corporation, who as a junior officer of the National Guard organized the first National Guard aero unit in this country in 1915, and who for years has been one of the most prominent advocates of aerial preparedness in America, was named in the list of missing cabled from France by General Pershing. Colonel Bolling is the highest ranking American officer to be reported in an American casualty list since the United States troops went into action.

Mrs. Bolling, who is at her home in Greenwich, Conn., said she had received no information other than that contained in General Pershing's cablegram and a notification from the War Department. She seemed to be hopeful that better news would be forthcoming within the next few days.

Colonel Bolling was born in Hot Springs, Ark., forty-one years ago, and is a Harvard graduate of the class of 1906.

In the Spring of 1915, Colonel Bolling, then a First Lieutenant in the Signal Corps of the National Guard of New York, organized the First Aero Company of the guard in this country. The company was mustered into the Federal service at the Garden City Aerodrome on July 13, 1916, following a period of training at the Hempstead aviation field. The organization of the squadron was made possible through the generosity of prominent New Yorkers who contributed $59,000, through the Aero Club of America, for its equipment. Of this sum Mrs. William H. Bliss gave $10,000 and William K. Vanderbilt $1,000.

Andes Mountains Crossed in Aeroplane

Lieutenant Cendelaria, of the Argentine army, April 15 crossed the Andes by aeroplane from Zapala, Argentina, to Curico, Chili, a distance of 180 kilometres (112 miles). The machine crossed the mountains at an altitude of 3,200 metres (10,500 feet).

This is the first recorded crossing of the Andes by aeroplane. On June 24, 1916, a balloon, operated by Captain Zuloaga and Engineer Bradley, crossed the Andes from Santiago, Chili, to Uspallata, Argentina.

Allan A. Ryan Named Police Defense Head

Allan A. Ryan, son of the late Thomas F. Ryan, and a member of the Board of Governors of the Aero Club of America, was appointed by Commissioner Enright as special deputy commissioner in charge of national defenses, without salary.

Mr. Ryan is the third millionaire to join the Police department without pay, the others being John A. Marris, special deputy in charge of traffic, and Rodman Wanamaker, special deputy in charge of the police reserves.

Since the war began he has taken a deep interest in the defense of the city. As special deputy commissioner he will be responsible for guarding the water fronts, docks, tunnels and bridges, in conjunction with Inspector Thomas V. Underhill, who has been in charge of the division of national defense.

Mr. Ryan is a native New Yorker. He was born here, May 5, 1879, and was educated at Stony Hurst Academy, England, and Georgetown University, Virginia.

Virginia-New York Flight in Liberty Plane

Driven by a Liberty motor at an average speed of 100 miles an hour, an army aeroplane arrived at Mineola from Langley Field, near Norfolk, Va. The time for the flight as given in a statement issued on March 15 by the Aero Club of America was three hours and fifteen minutes. The statement added that Major Roy S. Brown, an expert army pilot, and George Buzan, a Liberty engine expert, were the passengers. The distance between Langley Field and Mineola is about 325 miles.

The aviators started from Langley Field, near Norfolk, Va., at 11 o'clock sharp. Rising high, they reached a height of 12,000 feet after passing Baltimore. The air was exceedingly cold there, and they came down lower, and the flight averaged 6,000 feet for the rest of the journey.

They easily reached Long Island and found Mineola, and landed at Mineola Field No. 1, where they were received by Major Canady, Major Thomas Hitchcock, and other officers, who welcomed them.

Almost the first question asked of them as they landed was about the Liberty motor. The motor never missed a stroke during the entire trip. It is one of the motors made by the Packard Company, and both Major Brown and Mr Buzan were enthusiastic over the performance.

© Committee on Public Information

A "Blimp" doing its bit in the Liberty Loan drive over New York City. Thousands of appeal circulars were dropped over the city.

Major General Squier Detailed as Member of Joint Army and Navy Board

Washington.—By direction of the President, Major General George O. Squier, Chief Signal Officer of the United States Army, has been appointed a member of the Joint Army and Navy Board "on aeronautic cognizance." Colonel Henry H. Arnold has also been assigned to the same duty.

Official Review of Naval Aviation

Washington.—In an official statement for the "Official Bulletin" reviewing the year's war activity, the Navy Department makes the following report on naval aviation:

"There has been marked progress in the development of naval aviation. Orders have been given for sea planes, flying boats, dirigibles, and balloons. The above material is being built in private establishments and also at the naval aircraft factory in Philadelphia. This factory was authorized by the Secretary of the Navy July 27, 1917. On August 6 the first contract for factory buildings was let, and on August 10 ground was broken for the first building. The first machine turned out by this factory was completed on March 1. Additional machines will follow in rapidly increasing numbers until about June 1, when it is expected to turn out at least one complete machine a day.

"The outbreak of the war found the Navy well supplied with materials required for the then existing enlisted personnel and for the upkeep of the vessels of the fleet, a heavy demand having been anticipated.

"With the rapid increase in enlisted personnel, the laying down of additional destroyers and small craft, and the conversion of large numbers of merchant vessels, extensive additional purchases of all kinds of supplies, materials, and munitions were necessary. The demands for such additional materials have been successfully met."

Enemy Takes First American Aviator

Amsterdam.—The Germans have made their first capture of an American aviator, a semi-official Berlin despatch reports. He is said to have been shot down on the western front on Sunday.

The American aviator is described as an engineer by profession, who since September of last year has served with the French forces.

Aeroplane Mail Service in Russia

Washington.—A report has been received from Russia that the first aeroplane mail experiment from Petrograd to Moscow, a distance of 400 miles, was successful. The trip was made in 5½ hours, and 300 lbs. of mail were carried. Four aeroplanes now fly daily in both directions, and service to other cities is contemplated. The postage fee is $1 per letter.

Furniture Company Making Aeroplane Parts

Grand Rapids.—A new three-story addition to the Luce Furniture Co., to be used in the construction of aeroplane parts, has been completed.

© International Film

A French pilot about to start on a bombing trip over the enemy lines in Serbia paints his aerial bombs with the names of two American cities in honor of two Americans flying with the squadron

Piano Factories to Make Aeroplanes

Washington.—The War Industries Board reached an agreement with piano industries to curtail production 30 per cent in April and May so as to create additional facilities for aircraft work which the piano factories will take up. Priority orders have been issued in favor of lumber shipments from sawmills to the piano factories which will manufacture aeroplanes.

Board Appointed to Grant Air Licenses

Washington.—The board which will grant civilian licenses to operate aircraft has been announced. It includes Major-Gen. George O. Squier, chief signal officer of the army, as chairman. The other members are Col. H. H. Arnold, Signal Corps; Lieut-Col. Claude E. Brigham, Coast Artillery, and Capt. Noble E. Irwin; Capt. T. R. Y. Blakeley and Capt. F. H. Clarke to represent the navy.

All aviators except officers of the army and navy, must obtain licenses from this board for the operation of balloons, seaplanes or aeroplanes.

Aircraft Heads New Priority List

Washington.—The War Industries Board, of which Bernard M. Baruch is chairman, has issued what it terms "Preference List No. 1," which lists 44 trades that are to be given priority in the delivery of coal and coke. The list makes no mention of automobiles or trucks and the omission of these products is understood to have been because of the tacit agreement made the first week in March by which automobile manufacturers agreed to a reduction in output of 30 per cent and that they would be allowed sufficient fuel to produce the remaining 70 per cent.

The issuance of the list, which is essentially a revision and extension of lists previously issued by the Fuel Administration, is not causing any apprehension. Manufacturers believe that under the terms of the March agreement they will be permitted to get all the fuel they require. No interference with fuel deliveries has been felt to date.

Preference List No. 1 is "for the guidance of all governmental agencies in the supply and distribution by rail or water, or coal or coke." The statement issued with the list states that the board has not undertaken to classify any industry as non-essential or at this time to limit the quantity of fuel which any particular industry or plant shall receive. The industries which are listed "will be accorded preferential treatment by the Fuel Administration in the distribution of coal and coke. The same plan will be followed in according preferential treatment to war industries and plants in the transportation of raw materials and supplies." The statement makes plain that the Priority Commissioner may certify additional classes of industries and additional plants whose operation as a war measure is important. Following is a list of preferred industries:

List of Preferred Industries

Aircraft—Plants engaged exclusively in manufacturing aircraft or supplies and equipment therefor.

Ammunition—Plants engaged in the manufacture of ammunition for the United States Government and the Allies.

Army and navy cantonments and camps.

Arms (small)—Plants engaged in manufacturing small arms for the United States Government and the Allies.

Chemicals—Plants engaged exclusively in manufacturing chemicals.

Coke plants.

Domestic consumers.

Electrical equipment—Plants manufacturing.

Electrodes—Plants producing electrodes.

Explosives—Plants manufacturing.

Farm implements—Manufacturers exclusively of agricultural implements and farm operating equipment.

Feed—Plants producing feed.

Ferroalloys—Plants producing.

Fertilizers—Manufacturers of fertilizers.

Fire brick—Plants producing exclusively.

Food—Plants manufacturing, milling, preparing, refining, preserving, and wholesaling food for human consumption.

Food containers—Manufacturers of tin and glass containers and manufacturers exclusively of other food containers.

Gas—Gas producing plants.

Guns (large)—Plants manufacturing.

Hemp, jute, and cotton bags—Plants manufacturing exclusively hemp, jute, and cotton bags.

Insecticides — Manufacturers exclusively of insecticides and fungicides.

Iron and steel—Blast furnaces and foundries.

Laundries.

Machine tools—Plants manufacturing.

Mines.

Mines—Plants engaged exclusively in manufacturing mining tools and equipment.

Newspapers and periodicals—Plants printing and publishing exclusively newspapers and periodicals.

Oil—Refineries of both mineral and vegetable oils.

Oil production—Plants manufacturing exclusively oil well equipment.

Public institutions and buildings.

Public utilities.

Railways.

Railways—Plants manufacturing locomotives, freight cars and rails, and other plants engaged exclusively in manufacture of railway supplies.

Refrigeration—Refrigeration for food and exclusive ice-producing plants.

Seeds—Producers or wholesalers of seeds (except flower seeds).

Ships (bunker coal)—Not including pleasure craft.

Ships—Plants engaged exclusively in building ships (not including pleasure craft) or in manufacturing exclusively supplies and equipment therefor.

Soap—Manufacturers of soap.

Steel—Steel plants and rolling mills.

Tanners—Tanning plants, save for patent leather.

Tanning extracts—Plants manufacturing.

Tin-plate—Manufacturers.

Twine (binder) and rope—Plants producing exclusively binder twine and rope.

Wire rope and rope wire—Manufacturers.

The Multiple Storage Battery for Aeronautic Uses

Many necessary electrical appliances have recently been added to the list of aeronautical instruments and equipment, but the problem of providing the proper source of current for such accessories appears to have been avoided by most battery manufacturers. In the last three years many storage battery makers have, of course, made experiments in an effort to produce a battery suitable for use on aeroplanes, but the necessary high degree of reliability in addition to the desired light weight has been difficult to attain.

Experiments on lightweight batteries exclusively for aeroplanes have been made by Mr. N. D. Sturges, President of the Multiple Storage Battery Company of New York, with the result that a battery of exceptional merit has been perfected. This is a 12-volt 50-ampere-hour battery, which is said to be the first one to come within the 40-lb. weight limit set by U. S. Government specifications. Besides being the lightest practical battery of its capacity ever built, its ability to stand up under severe conditions of service imposed upon it for starting, lighting, ignition and wireless, makes it particularly suitable for aeronautic use.

The multiple battery is of approved construction, assembled in separate hard-rubber jars, and follows the standard method of automobile starting battery construction. The improvement which has made its production possible lies in the manufacture of a light-weight battery plate which has more capacity than the ordinary plate used in starting batteries, and the same durability. The battery is capable of a steady current output of 20 watt hours per pound of element, which is far in excess of any other battery, and 50% lighter in weight than the average automobile starting battery.

The principles of construction are not entirely new, as they have proven their good qualities in giving constant satisfaction over a period of years. Overall dimensions of multiple storage battery for aeronautic use are: Length, 9¾"; width, 6½"; height, 8¼". The plates are 1/16" thick, 9 to a cell and six cells to a battery, i.e., 54 plates.

The production of a battery of such desirable characteristics furnishes a practical source of current for all electrical equipment desired on aeroplanes and opens up a new field of development along this line. This radical departure of cutting down the weight on storage batteries should aid materially all aeroplane builders because of the importance of reducing weight to a minimum.

Chanute Field News

Rantoul, Ill.—Lieut. Col. Fredrick M. Jones, who has been in command of the Chanute Aviation Field since last fall, has been ordered, with several other aviation officers, to over seas service. Colonel Jones has already left Chanute Field. Other aviation officers who is accompanying the Chanute chief are Major W. B. DeArmond, commander of the Scott Field at Bellville, Ill., and Major Owen Aleshire, commander of the Hazelhurst Field at Mineola, N. Y. A remarkable coincidence is that these three officers are old pals and were for many years together in the Twelfth Cavalry.

Major George Krapf, who has been stationed at Wichita Falls, Texas, has been ordered to Chanute and will have command of the local flying field. Major Krapf was formerly the commandant of the United States School of Military Aeronautics at the University of Illinois and is a West Point graduate.

Twenty non-flying officers from here have been ordered to the Armorers' School, which has been established at the Wilbur Wright Flying Field at Dayton.

Secretary of the Treasurer McAdoo has requisitioned the services of Major Maurice Connolly, one of the officers of Chanute Field. Major Connolly is desired to assist in the campaign for the Third Liberty Loan for a period of two weeks after April 15, and Secretary of War Baker has granted this request. Major Connolly, who is a former Congressman from Dubuque, Ia., has been in Washington, D. C., on leave following a long illness.

"Garabed's" Fate to Be Settled

Washington, D. C.—The long expected demonstration of "Garabed," that machine which it is expected to grasp unlimited energy from the air and distribute it cheaply for a multitude of power units, is, according to its inventor, Garabed T. K. Giragossian, about to take place.

The machine has been almost wholly rebuilt for the purpose. Giragossian states that he is not permitted to divulge the time or place.

Georges Carpentier Recovering from Aero Accident

Georges Carpentier, champion French heavyweight pugilist, who is recovering from wounds in the head, sustained during an aeroplane accident, has given up all thought of coming to the United States to box during the period of convalescence and will devote his time to teaching physical culture and boxing at the Normal Gymnastic School of Joinville.

Wardrop Lectures to Many Organizations

During the last few days G. Douglas Wardrop, editor of Aerial Age, has lectured on aircraft in warfare to the following organizations and clubs: The Alumni Society of Columbia University, the Twilight Club, the Rainy Day Club, the American Society of Mechanical Engineers, the Society of Engineers of Eastern New York, and the Boston Engineering Society.

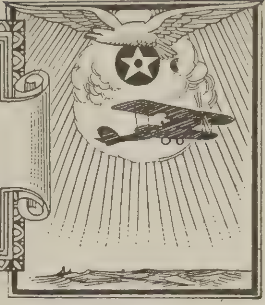
NAVAL and MILITARY AERONAUTICS



Key to Abbreviations

AAD—Assigned to active duty.
ADO—Report to Aviation Supply Depot, Dayton, Ohio.
AEF—On duty with the American Expeditionary Forces.
AGC—Report to Aviation Supply Depot, Garden City, L. I., N. Y.
AHT—Report to Aerial Gunnery School, Houston, Texas.
AMV—Report to Aviation General Supply Depot, Morrison, Va.
AOV—Report to School for Aerial Observers, Hampton, Va.
APR—Report to School of Aerial Photography, Rochester, N. Y.
BST—Report to Brooks Field, San Antonio, Tex.
CAF—Report to Carlstrom Field, Arcadia, Fla.
CAG—Report to Camp Hancock, Augusta, Ga.
CAP—Commissioned as Captain, Aviation Section, Signal Corps.
CCI—Report to Chanute Field, Champaign, Ill.
CDT—Report to Aviation Concentration Camp, Dallas, Texas.
CGC—Report to Aviation Concentration Camp, Garden City, L. I., N. Y.
CGS—Report to Aviation Concentration Camp, Greenville, S. C.
CWJ—Report to Camp John Wise, San Antonio, Tex.
CLR—Commissioned as Colonel, Aviation Section, Signal Reserve Corps.
CMV—Report to Aviation Concentration Camp, Morrison, Va.
COL—Commissioned as Colonel, Aviation Section, Signal Corps.
CPR—Commissioned as Captain, Aviation Section, Signal Reserve Corps.
CRI—Report to Chanute Field, Rantoul, Ill.
CSO—Report to the Chief Signal Officer, Washington, D. C.
CUI—Report to School of Military Aeronautics, Cornell University, Ithaca, N. Y.
CWT—Report to Call Field, Wichita Falls, Texas
DAF—Report to Door Field, Arcadia, Fla.
DIK—Report to Camp Dick, Dallas, Tex.
DIS—Honorably discharged from service.
EEP—Report to Essington Field, Essington, Pa.
ELA—Report to Eberts Field, Loanoke, Ark.
EOT—Report to Ellington Field, Olcott, Texas.
FLR—Commissioned as First Lieutenant, Aviation Section, Signal Reserve Corps.
FLT—Commissioned as First Lieutenant, Aviation Section, Signal Corps.
FOB—Report to Fort Omaha Balloon School, Omaha, Neb.
FRF—On duty requiring regular and frequent aerial flights.
FSO—Report to Fort Sill School for Aerial Observers, Fort Sill, Okla.
GIT—Report to School of Military Aeronautics, Georgia Institute of Technology, Augusta, Ga.
GLC—Report to Gerstner Field, Lake Charles, La.
HHN—Report to Hazelhurst Field, Mineola, L. I., N. Y.
JHU—Report to School of Military Aeronautics, John Hopkins University, Baltimore, Md.
JMA—Rated as Junior Military Aviator.
JRC—Report to Jackson Field, Riverside, Cal.
KST—Report to Kelly Field, So. San Antonio, Tex. (When specified in the order, the number of the field is given in parantheses)
LDT—Report to Love Field, Dallas, Tex.
LHV—Report to Langley Field, Hampton, Va.
LTC—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Corps.
LTR—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Reserve Corps.
MAJ—Commissioned as Major, Aviation Section, Signal Corps.
MDO—Report to McCook Field, Dayton, Ohio.
MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MMP—Report to Middletown Aviation Supply Warehouse, Middletown, Pa.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PRC—Appointment to Aviation Section declined; prefers retaining previous commission.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
PWM—Report to Payne Field, West Point, Minn.
REL—Relieved from present duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRV—Report to Richmond Aviation School, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
TFT—Report to Taliaferro Field, Fort Worth, Texas. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UCB—Report to School of Military Aeronautics, University of California, Berkeley, Cal.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WAC—Report to Aviation Concentration Camp, Waco, Tex.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WFO—Report to Wilbur Wright Field, Fairfield, Ohio.

Note 1.—Report to points named for temporary duty in the order given.
Note 2.—Report to Chicago; Fort Worth, Tex.; EOT; Note 1.
Note 3.—Report to engine and repair depot, Dallas, Tex.
Note 4.—Report to Dayton, Ohio; then Chief Signal Officer, Washington.
Note 5.—Take station at Detroit, Mich.
Note 6.—Report to Indianapolis, Ind,
Note 7.—Report to district manager of Equipment, 104 Lindsey Building, Dayton, Ohio.
Note 8.—Proceed to Fort Monroe, Va.
Note 9.—Report to chief, military intelligence section, General Staff, Washington, D. C.
Note 10.—Report to commanding general, Eastern Department, New York, N. Y.
Note 11.—Report to commanding officer, Western Department, San Francisco, Cal.
Note 12.—Report to general supply depot, Atlanta, Ga.
Note 13.—Report to Duesenberg Motors Corporation, Elizabeth, N. J.

ON MOMENTS OF INERTIA*

By T. H. JONES, B. Sc., A. M. I. M. E.

AN accurate knowledge of the methods of finding the moment of inertia is of very great importance to the designer and stress-draughtsman in almost any branch of engineering, and this is particularly so in a few of the more modern branches where maximum strength must be consistent with minimum weight. In many of the easier and regular shapes of sections the moment of inertia (I) can be readily found by calculation which ensures a good degree of accuracy; but quite a large number of shapes of sections in common use are such that for accuracy the methods of calculation would not be practicable. For these different sections I is usually found graphically, and almost any text-book will provide some method of doing the work; but the methods generally suggested, however, are often difficult to use and liable to inaccuracy. The following method is about the best, and it can be recommended for its simplicity and general reliability. To find the I of any section, draw out the section, then cube all the ordinates with the neutral axis as base. Complete the figure formed by these ordinates, and find the area enclosed by the curve so drawn. One-third of this area = I of this section.

I BEAM SECTION.

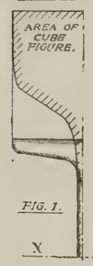

FIG. 1.

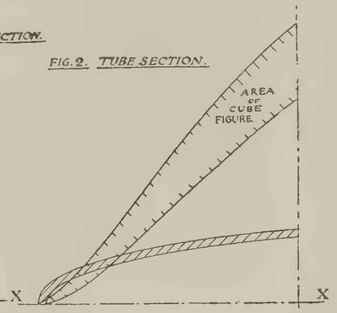

FIG. 2. TUBE SECTION.

Very often the section has to be drawn to some scale, and this must be accounted for in the estimate of I.

As an example, take a 5-in. × 3-in. I beam section the linear dimensions of which were drawn full size. (Fig. 1.) Since the section is exactly symmetrical only a quarter need be drawn. By means of a table of cubes found in most pocket books the lengths of the ordinates from the neutral axis are cubed, and for convenience are set out one-third size, the cube figure being distinguished by the open shading.

To Find the I of the Whole Section of the Beam

We find the area of this cube figure by means of a planimeter to be 3.4 sq. ins. Now the cube scale is one-third (Linear Scale:—full size), therefore I of whole section about XX is given by:—

$$\frac{3.4 \times 4}{3} = 13.61 \text{ (ins.)}^4,$$

which corresponds to the figure given in the particular pocket book of standard sections for this size of section, *i.e.*, 5 ins. × 3 ins.

As a further example, take an oval-shaped tube. (Fig. 2.)

This was drawn 4 × actual size, but because of symmetry again only one-quarter was drawn.

The cube figure was drawn in the usual way, *i.e.*, the *actual* ordinates are cubed and then drawn to scale 100 times full size for convenience. The area of the cube figure for the *whole* section = 5.59 × 4.

Now linear scale = 4. Cubes scale = 100.

∴ I of whole section about axis XX

$$= \frac{5.59 \times 4}{3 \times 100 \times 4} = .01863 \text{ (in.)}^4.$$

If the section be not symmetrical then the C.G. must be found, through which the neutral axis is then drawn and the cube figure constructed in two separate portions, the one above the axis and the other below it.

This method can be used for any shape of section, to find the I about any axis of bending; it is quick and accurate, simple and straightforward, and is certainly not so well known as its usefulness would warrant.

For circular sections of rods, tubes, etc., the I of the sections is easily calculated from the ordinary rule:—$I = \frac{\pi}{64}(D^4 - d^4)$, where D = outer, and d = inner, diameters respectively. Many pocket books give a list of values of I for circular sections which is undoubtedly of much use.

The usefulness of such a table is, however, considerably lessened when the gauge of a tube, say, is such that the inner diameter becomes an odd size, although the outer diameter may be quite an even figure. To overcome this difficulty and to save time in geting out the values of I for such sections, the accompanying graph (Fig. 3) has been made, showing values of I of circles of diameter .2 in. up to diameter 2.0 ins. They are plotted in such a way that a good degree of accuracy may be obtained by mere inspection of the graph. It will be seen that the scale of I is not constant, and consequently the values of I are written on the curves themselves, but the curves themselves are all successively continuous. As an example of one of the many uses of such a graph, take the case of a metal tube having an outside diameter of .875 in., and gauge thickness = 20 = .036 in.

Therefore inside diameter = .803 in.

From the graph the I corresponding to a diameter .875 in. = .02876, and I corresponding to diameter .803 in. = .02038.

Hence nett I of tube = .02876 — .02038 — .00838 being the difference.

Conversely knowing the value of I for a tube, which will suit the particular job in hand, then the diameter and gauge can easily and quickly be found by reference to the graph.

If the polar moment of inertia of any circular section be required, this is equal to twice the I about a diameter.

The usefulness of such a graph like the one illustrated in Fig. 3 is considerable, but for those who would prefer to interpolate, the tabulated values of I are here given, together with the corresponding diameters.

This system of graphing has wide application where accurate readings are required by mere inspection and it is for the readers themselves to apply the method to their own particular needs.

THE ARTIFICIAL SEASONING OF WOOD

By Professor PERCY GROOM, D.Sc., F.L.S.*

THE seasoning of timber is in essence a post-mortem process of drying conducted in such a manner as to permit of the wood being used as a structural material. It is necessary to emphasize the fact that the process is one conducted after the normal vital activity of the tree has been arrested, because it has been seriously but entirely erroneously urged in the courts of law that the term "mature" as applied to timber is a synonym of "seasoned."

In order to devise perfect methods and apparatus for artificially seasoning timber, it is necessary to understand the physical principles determining the drying of any material and the practical application of these to ensure equable distribution of heat and moisture among the drying objects. But it is also necessary to have full knowledge of the structure and properties of wood, as well as the effects induced in these properties induced by change in the amount of water contained in the wood.

Construction of Wood

Wood is not a material; it is a structure, and varies in design and construction not only in the different kinds of timbers, but also in wood produced by one and the same species of tree. It is essentially composed of a material, allied to cellulose, that may be termed *wood-substance*, which is excavated into countless minute closed cavities of various shapes.

The structural constituents of wood thus are all hollow and shaped like narrow spindles, tubes, or bricks; their solid parts, composed of wood-substance, are termed "walls." Those constituents mainly dovetail with one another and their long axes are mostly parallel to the original long axis of the trunk or branch of the tree. But this main grain of the timber is crossed at right angles by bands of weak brick-shaped constituents; as these bands in the original trunk run transversely in a radial direction, they are termed "rays." Such rays are familiar as the cause of the silver grain of oak, beech, mahogany, and other woods.

These various structural constitutents may contain in their cavities air, water, and substances dissolved in water, small quantities of various solids and occasionally resin, which is often contained in special local spaces created by the local separation of the structural constitutents. The solid walls contain water and relatively small amounts of various complex organic substances.

From the present standpoint a piece of wood may be regarded as being composed solely of wood-substance, water, and air, for the other substances present represent only an insignificant fraction of the weight of the whole.

Water in the Green (Fresh) Wood

In the trunk of a sufficiently mature standing tree a considerable amount of water is contained in the outer wood (*sapwood*) and usually a smaller amount in the central wood (which, when differing in color from the outer wood, is termed *heartwood*). For instance, in the Scots pine (red deal) the sapwood is on the average about four times as moist as the heartwood. In other cases (*e. g.*, the oak) at times the sapwood and heartwood may contain almost equal amounts of water.

The Drying of Wood

The water present in the cavities (as opposed to the walls) can pass freely along the cavities and through the walls, so that when wood is dried this water readily evaporates, and a piece of wood containing more than 100 per cent (the percentage of water is best expressed as a percentage of the weight of the absolutely dry wood in which it was originally contained) of water is easily dried to a condition when the water is solely in the walls, and amounts to 25 to 30 per cent. Yet during the phase of drying, if the wood is being artificially seasoned at a high temperature, two opposite effects and defects may be induced so that ruptures arise in the wood. On the one hand, the rapid production of steam inside the closed hollow constituents creates pressure that suffice to burst the little chambers open and cause large splits in the timber. On the other hand, the drying timber may collapse along its grain; this collapse may be due to the evaporation of water from the hollow closed constituent being accompanied by little or no admission of air, until a thin film of moisture remains lining the wall; this film, by its contraction due to surface tension, exerts on the wall a pull that culminates in collapse.

After the evaporation of the water contained in the cavities of the remaining water is held with considerable force by the wood substance (walls), which therefore may be loosely described as being a hygroscopic material. Wood-substance, like a number of other organic materials (glue, gels, and so forth), shrinks when it loses water, and swells when it absorbs water. Thus, at least in very thin drying pieces, wood does not begin to shring until it contains 25-30 per cent of water, and if it were possible to regulate the loss of water from a drying piece of timber so that the evaporation was balanced by an equal flow of water from the interior, no shrinkage would take place until all the water in the cavities has been removed. Indeed, in the cases of many timbers no perceptible shrinkage takes place during the early phases of seasoning; when once the cavities have been depleted of water shrinkage begins, and is henceforth proportional to the amount of water lost.

Assuming that a piece of wood, not too thick, has reached this critical point and is exposed to the atmosphere at normal temperatures, it will continue to give off water vapor until the water in the wood-substance (at any rate at the surface) is in equilibrium with the atmospheric moisture. This stage is reached, in our country, in the open air, but under cover when 17-22 per cent of the moisture is present. When brought into drier outhouses the wood becomes more fully seasoned and its humidity sinks to 13-17 per cent, while after being kept in rooms at least intermittently warmed, it attains a degree of dryness at which only 10-13 per cent of water is present. But in none of these cases is a final permanent degree of humidity attained; increase and decrease in the relative humidity of the atmosphere cause the wood respectively to absorb and emit water. It is partly to avoid such changes in the water-contents of wood, and the consequent changes of shape and size, that wooden articles are frequently coated with more or less impervious layers of varnish, paint, oil, paraffin wax, and so forth.

These various percentages of moisture therefore indicate the degrees of humidity to be aimed at in the artificial seasoning for articles that are to be used in the corresponding situations. Such is the usual *rationale* of the condition attained by naturally seasoned wood. There are, however, considerable qualifications to be added. On the other hand, it is known that in houses massive beams of oak, hundreds of years old, have been found to contain much moisture at the centre; it is also known that articles of oak, however well seasoned, when their surfaces are replaned "mover" and may crack at the surface. Those facts suggest that at least certain kinds of wood tend to acquire a relatively impervious surface, and that the inner wood in thick pieces of timber always contains a larger amount of water than corresponds to equilibrium with the local atmosphere.

Shrinkage and Warping of Wood

The shrinkage or swelling of wood-substances (walls of the constituents) occasions corresponding changes in dimensions of a piece of wood. These changes in dimensions are not equal in different directions, and therefore tend to be accompanied by changes of shape of the piece of wood. The cause of this lies in the hetrogenous structure of the latter. The elongation of the constituents along the grain causes a distinction between the transverse and longitudinal structure. The occurrence of the rays, and the concentric construction of the successive layers of wood, evoke differences in circumferential and radial structure. Shrinkage and swelling are unequal in all these cardinal directions; along the grain (longitudinally), and transversely in the radial and circumferential ("tangential") directions.

The fibres and other structural constituents of wood, like vegetable films in general, shrink and swell much less along their long axes than transversely. In drying from the green to the fully-seasoned conditions, wooden rods cut along the grain, transverse-radially, transverse-tangentially, usually show respectively the following shrinkages recorded in percentages of the original length 1, 3-5, and 6-10. The greatest cause of warping and splitting during drying is the disproportionately large circumferential (tangential) shrinkage when compared with radial shrinkage.

If we consider the seasoning of the trunk of a tree, it might appear impossible to secure this without the wood splitting, since the circumference tends to shring twice as much for each end of length as does the resin. But wood is both extensible and plastic, so that a beam loaded at the centre acquires a permanent set; hence it is possible to season wood without distortion or splitting, despite the tendency towards differential contraction.

If a piece of wood be dried too rapidly, so that the outer layers tend to shrink too quickly when compared with the inner wood, one of the following results ensue: either the piece warps or splits at the surface, or it undergoes a change known as case hardening, or there is a combination of these effects.

Case Hardening

Case hardening is almost universal in wood that has been seasoned too rapidly in a drying kiln. The name is appropriate, because where these defects exist the wood at and near the surface is different from that lying within, and, so to speak, forms around this a hard case. The wood is harder than if properly seasoned. It may or may not display superficial cracks or internal cavities that are pointed-oval in a section across the grain of the wood. When such wood that has been fully dried throughout is planed along one face, it bends, becoming concave on the newly exposed surface, or if it be sawn through the middle, the two halves bend so that the fresh surfaces are concave. If, however, the hard case possesses well-developed cracks these curvatures do not take place. The *rationale* of these phenomena is as follows:—During rapid drying the superficial wood dries more rapidly than the water is supplied to it from within. It therefore tends to shrink, but its contraction is opposed by the internal wood, which has not lost sufficient moisture to cause it to shrink at the same place (if at all). The inner wood, therefore, is in a condition of compression, while the outer wood is in tension. The latter being ductile resists rupture but acquires a permanent set. The hard case of wood thus formed opposes the outward passage of water, so that the internal wood dries more slowly and accordingly tends to shrink more. Eventually a stage is reached when the inner wood has lost so much water that it tends to contract more than did the outer wood, so that the conditions of stress are now reversed, the outer wood being in compression and the inner in tension. As a consequence at this phase internal splits may arise, and widen out to form the oval "honeycomb" cavities already mentioned. Wood completely dried continues to retain this peculiar stressed condition (excepting in so far as it is relieved by splits), and therefore bends *instantly* as it leaves the saw or planing instrument. Such bending differs from warping, which is caused by lack of uniformity in the distribution of moisture at the time of bending, and is the gradual result of differential tension caused by subsequent drying. A succession of the two kinds of bending takes place if a piece of wood in the first stage of case hardening be sawn through; for the newly exposed inner damp wood, liberated from its condition of compression, elongates, whereas the hard "case" remains constant in dimensions, with the consequence that the freshly exposed surface becomes convex. But as the wood dries the convexity changes to straightness, and finally to concavity as the damp wood dries. During the initial stages of case hardening, shallow cracks may arise in the outer hardening wood and partially relieve the tension. Such cracks may be subsequently closed in the second stage, when the hard case is in a condition of compression.

Warping and Splitting

The elementary facts in relation to the different amounts of shrinkage in the three cardinal directions fully explain such phenomena as the lack of warping in quartered or rift-sawn wood, the excessive warping or splitting of wood with curved grain (including burr wood), and partly justify the use of three-ply wood. Yet there remains many problems requiring solution as to the proneness of certain kind of timbers to warp or split, and to the causes determining whether a wood shall merely warp or merely split or display both these defects.

Mention may now be made of a special additional case illustrating the effect of the mode of cutting timber in determining whether or not the latter will be successfully kiln-dried. In certain types of exotic timbers the grain, in place of being straight, runs in successive layers alternately in right-handed and left-handed spirals, with the result that in a bastard-cut board the grain is not only oblique, but also appears to be interlocked. Such wood is truly cross-grained. A bastard-sawn board, when rapidly dried, is apt to twist, because longitudinal shrinkage on each face is least along the direction of the prevailing grain. When the effects on the two faces of the board agree in sense, a twisting couple is established. The prevention of this lies in cutting the trunk radially into boards—*i.e.*, producing solely quarter-sawn boards.

Amount of Shrinkage

Under like conditions the shrinkage (or swelling) of different kinds of timbers, of different samples of the same timber, or even of the various constituents of one piece of timber, is not the same. Taking the last case first, certain softwoods (coniferous timbers), when properly kiln-dried, or when installed in an incompletely seasoned condition as panels, become ribbed along the grain. The ridges and furrows correspond to alternating layers of light spring wood and heavy summer-wood, which have shrunk unequally.

---

* Paper read before the Institute of Automobile Engineers

It is often alleged that heavy woods shrink more than do light ones. This statement, though not devoid of some foundation, is often opposed to the truth. But to understand the matter fully it is necessary to consider the precise significance of the terms "heavy" and "light" as applied to woods.

Wood-substance composing the solid framework of all timbers is, within very small limits of variation, invariable in specific gravity (.56), being slightly more than half as heavy again as water. Hence, in comparing two pieces of wood of equal volumes and deprived of all water, the one is heavier than the other (almost) solely because it contains more wood-substance and less air. Consequently, when two pieces of wood of different (apparent) specific gravity, but containing the same percentage of water, are being seasoned, the amount of water lost during drying down to the same percentage of humidity is proportional to the apparent specific gravities of the two woods when absolutely dry. Thus for this reason alone a heavy wood seasons more slowly than a light wood under identical circumstances. Obviously, also, if a heavy wood and a light wood are first deprived of all the water in their cavities, subsequently the comparative amounts of shrinkage of the wood-substance of the two will be proportionate to their (dry) specific gravities, assuming that they ultimately contain the same percentage of water. This might cause us to anticipate that a heavy timber would shrink more than a light one. Moreover, it has been found that specimens of wood rapidly dried in an oven at a high temperature shrink less than specimens of the same kind of wood that are dried more slowly. This fact (which as a generalization requires confirmation) might lead us to anticipate that the slowly drying heavy timber would shrink more than the more rapidly drying light one. But these anticipations leave out of count the fact that the minute architecture of different timbers varies widely. Thus the generalization in reference to the great shrinkage of heavier woods is not true. It is, however, the fact that the lighter softwoods season more rapidly and shrink less than the heavier hardwoods. Moreover, the shrinkage of different samples of the same kind of wood, and to some extent of different kinds of timber that are structurally very similar, is often proportional to the apparent specific gravity. The lightweighted wood of Weymouth pine (Canadian white or yellow pine) shrinks less than the heavier Scots or Baltic pine (red deal); in this case probably also because the former is richer in rosin, which decreases shrinkage.

The preceding remarks at least partially explain why softwoods (coniferous timbers) are more easily and rapidly seasoned than are hardwoods, without inducing distortion and cracking, and why the seasoning can be conducted safely at higher temperatures in the case of the former timbers.

The structure of softwoods is relatively simple, for the timber is mainly composed of spindle-shaped fibres, which differ among themselves almost solely in that the spring-wood fibres have wider cavities and thinner walls than have those of the summer-wood. Moreover, the rays crossing these fibres at right angles are extremely thin, and consequently disturb the straight course of the fibres to a minimum extent.

Hardwoods, on the other hand, are complex in structure, and consist of various structural constituents that vary greatly in shape, width and thickness of wall. These include long thin-walled relatively wide tubes, varied fibres, and very short, often thin-walled brick-shaped constituents. Crossing these are the rays, which may be so thick (*e.g.*, in oak) as to necessitate the curving of the grain round their flanks.

Objects and Effects of Seasoning

The objects and effects of seasoning wood are:

1. To decrease its weight.
2. To decrease its shrinkage, warping, and splitting when the wod is utilized for its final purpose.
3. To increase its strength (especially in compression), its limit and its co-efficient of elasticity, and its hardness (when measured by indentation).
4. To decrease its pliability and toughness both below and above the limit of elasticity.
5. To increase the power of resistance of the wood to decay.

A piece of timber by its loss of water during seasoning may lose more than 50 per cent of its original weight, and may gain 100 or over 200 per cent in strength. But when the seasoning process is carried far, however carefully this be done, wood tends towards brittleness. On the other hand, if one wishes to increase the pliability and plasticity of wood one heats and moistens it, so that prolonged treatment with steam renders wood very pliable and plastic, and thus tends permanently to rob it of a portion of its elasticity. The significance of these facts will be evident when the different processes of artificial seasoning are considered.

Natural and Artificial Seasoning

In *natural seasoning* the sun's rays constitute the source of heat, and natural atmospheric currents contribute to the drying process. In correspondence with the variation in climate and weather, the process is irregular and unregulated, sometimes being in abeyance and at some other times being too rapid. The timber is consequently liable to warp and split, to undergo decay, or to be attacked by boring insects. Yet natural seasoning, despite of its wastefulness and long duration, has one advantage: it yields wood mechanically superior to wood that is artificially seasoned by any but the best processes.

Artificial seasoning usually takes the form of *kiln-drying,* in which the source of heat is artificially induced currents of air of regulated humidity. When properly carried out it saves not only time but also material, and may yield wood perfectly suited for its ultimate purposes. In the past, however, artificial seasoning has been mainly applied to wood destined for use in furniture and other objects, in which standing qualities were the main feature aimed at, and in which mechanical defects, such as brittleness, were not of paramount importance. It may be stated now that although artificial seasoning has been so successfully applied to certain kinds of timber that there is no evidence of any inferiority to naturally seasoned wood, much research and experiments will be required before we know how to accomplish this in the most safe and efficient manner in connection with other timbers.

Artificial Seasoning—Four means of regulating the evaporation of water from timber are available for use:

1. Supply of artificial heat.
2. Production of air currents.
3. Regulation of the humidity of the air.
4. Regulation of the pressure of the air (rarefaction).

Excesses in any of these is liable to cause the wood to be damaged or to delay the seasoning.

Early in the history of mankind the seasoning effect of *artificial heat* must have been discovered, for green sticks held in front of a fire become hard and strong, while various articles made in primitive fashion in the forest of freshly-felled beech are even in modern times hardened by holding them in the fumes rising from burning wood.

From such primitive beginnings there is but a slight step to the earliest types of *drying kilns,* in which the timber was contained in a room, at one end of which was a furnace that was separated from the timber only by a screen; or the room possessed a perforated floor below which was a furnace burning sawdust, shavings and fragments of wood. Obviously in such cases, although ventilating chimneys were provided, uniform distribution of heat and uniform drying were impossible, and the wood near the source of heat dried too quickly and was largely spoilt.

Relatively ineffective was the mere placing of the heating arrangements outside the drying chamber, for again the timber packed towards the centre dried more slowly than that outside.

Stewing or Prolonged Steaming of Wood

Before passing to the more modern types of seasoning kilns mention may be made of another process of dealing with green wood by means of heated water-vapour with no ventilation. The pieces of wood are piled directly on one another in a chamber that can be hermetically closed. After closing the chamber hot water-vapour, at a temperature above 30° C., is admitted from numerous holes in a tube. This vapour penetrates the wood, condenses, and causes an outflow of colored sap, which sinks into the concave floor of the chamber. When the requisite pressure has been attained the steam pipes are closed for four or five hours. Thereafter the colored thick brown sap is evacuated through an outflow pipe. The process is repeated until the sap flowing out and condensing is colorless; this stage being reached in four to five days. The door and escape shaft are opened to admit a free current of air and to allow the wood to cool. Thereafter the wood is transferred to a drying kiln or allowed to dry for a longer time at normal temperatures. The wood thus treated is seasoned in about four to five months instead of the two or three years that would be required for natural seasoning. Its properties are changed: sometimes its color is clearly modified, it is easier to work, warps less, and is said to possess increased powers of resisting, not only decay, but also attacks by insects. The treatment is akin to the prolonged steaming process by which beech wood is so changed that it loses its natural tendency to warp and split and acquires such redness of color as to facilitate its use as a substitute for mahogany.

Such processes of steaming are quite different from, and more prolonged than, those employed in rendering possible the permanent bending of beech and ash, or permanent compression of oak for railway keys.

The change in color that may take place in drastically steamed woods is thus accompanied by change in the properties of wood. These easily detected modifications are at least often paralled by changes in the chemical composition of the steamed wood. Mere boiling water relatively soon breaks down wood-substance partially and causes the production of cellulose (cj. cotton wool), and hot steam occasions the same chemical degradation.

Thus, in considering the possible effect of steaming processes freely employed in certain drying kilns, it has to be remembered that steaming tends to soften wood, renders it temporarily pliable, and so robs it of its elasticity as to make it into a plastic material.

Mechanical Effects of Different Methods of Heating Timbers

Having considered the more obvious effects of the application of dry heat and of steam on wood, it is possible to view in greater detail some results obtained in experiments performed under the auspices of the Forestry Service of the United States on woods to which heat and moisture were applied in various ways. The accompanying table gives some of the results obtained:

In the columns headed "Compression" and "Bending" are given the percentage changes in strength when compared with the wood naturally seasoned to the same degree of humidity: (*a*) denotes a gain in strength; (*b*) a loss; (*c*) no change. The columns headed "dry" refer to wood which was first naturally seasoned, then in this condition was subjected to the particular treatment indicated, and thereafter finally naturally seasoned for one year, and finally tested. The columns headed "Soaked" refer to wood which was naturally seasoned, then soaked with water, and in this wet condition was subjected

*Plus 26 day at 145° Fahr.

to the treatment indicated, and subsequently tested after a year's natural seasoning.

The results of these tests may be summarized as follows:

Exposure to a temperature of 145° F., with dry air or exhaust steam, for nineteen to twenty-six days had little effect on the compressive or bending strength of the two timbers. An additional couple of days in exhause steam or an additional eight days of dry heat at 170° F. evoked signs of weakening.

Shorter exposures to saturated steam at 212° F. (for up to four hours) or superheated steam at atmospheric pressure at temperatures 274° F. and 331° F. (for four and six hours respectively) caused no injurious effects.

But immediately that saturated or superheated steam at high temperatures, with the pressure at 30 lbs. or more, is applied, weakening of the timbers quickly ensued. In saturated steam at 274° F. at a pressure of 30 lbs., pine was in four hours weakened about 10 per cent; at 331° F. and 90 lbs. pressure, ash was in five minutes weakened 4 per cent, and in one hour 27 per cent; while the pine was weakened 9 per cent in fifteen minutes and 42 per cent in four hours.

But when the ash was subjected in its soaked condition to saturated steam at 331° F. with the pressure at 90 lbs., no ill effects resulted; yet under the desiccating influence of superheated steam at the same temperature, but at atmospheric pressure, a weakening took place.

The significance of these results, particularly in relation to speeding up of artificial seasoning processes, is obvious, but is of limited scope, since these tests were merely static and gave no indication as to the shock-resisting powers of the treated woods. Tiemann, however, in giving an account of this research, states that the woods subjected to the high temperatures were more brittle than naturally seasoned.

Another effect of most of the treatments recorded in the table was that the woods treated subsequently showed reduced warping and shrinkage when compared with naturally seasoned wood. An abnormal darkening of the color of the wood was evident, especially when high temperatures were used.

Before passing away from the consideration of the effect of damp air upon wood, it may be mentioned that when the air is damp but merely warm, not only is the desiccating action low or non-existent, but the conditions favor the growth on the wood of moulds and more virulent wood-destroying fungi. And there are on record cases in which seasoning timber or the woodwork of kilns have been damaged through this cause.

It is now obvious that each kind of timber must be treated in a special manner, and that the precise seasoning treatment of one and the same kind of timber will vary with the dimensions of the pieces to be seasoned and with the amount of water that they contain. Moreover, one piece of wood may consist partly of sapwood and partly of heartwood, and the latter will dry more slowly than the former. Moreover, no two planks from one tree contain the same percentage of water, and a single plank may show considerable inequalities of moisture along its length and always does show such inequalities at different distances from the surface.

Considerable amount of experiment and research will have to be undertaken before the practical solution of these difficulties is accomplished for various kinds of woods.

It is, however, evident that in a kiln it is necessary to ensure approximately equal heating of all the pieces of wood and equable removal of water from them. These aims are best accomplished by the supply of hot air that shall be freely supplied to all points of each piece of wood. Two methods widely differing in design are in use:

1. In one the timber is ranged in layers tier upon tier, each being separated by a short distance from a corresponding layer of steam-heated pipes. Here the air is heated inside the kiln.
2. In other types hot air is admitted to the kiln from the floor or walls or from the end. Most of the modern kilns belong to this type and may be ranged into two sub-types:
   - (*a*) The chamber or compartment type
   - (*b*) The progressive or tunnel type.

The chamber type is illustrated by the *Sturtevant Kiln*, which in its completest form has three main air-distributing ducts, supplying respectively warm dry, cold dry, and moist air. Branch ducts from each of these connect with each department or chamber, if there be more than one of these; the supply of air is regulated by dampers. The process of drying is as follows:

1. Admission of moist cool air
2. Maintenance of humidity while the temperature is raised
3. Decrease in the relative humidity of the air and further rise of temperature

Circulation of the air is secured by fans, one of which takes fresh air, a part of which passes into the cold air ducts, and the rest passing through the heater and thence to the hot air duct. Another fan takes moist air from the chamber containing the wood and conveys any required amount of it to the moist air duct. Additional moisture may be liberated in the drying chamber by means of sprays.

Kilns of the compartment or chamber type are well fitted for simultaneously seasoning pieces of wood of various dimensions and even of different kinds. It is simple also to use in them autographic recorders of the temperature and humidity, so that model charts can be constructed to serve as guides for future operations. One other advantage is that the air currents are under control in all weathers and at all seasons.

In the tunnel type of kiln the timber is placed on trolleys and is moved forward along the tunnel day by day in the face of a current of air that meets it. This current of air is driest as it enters, and gains in moisture as it passes over the seasoning wood, and, therefore, moistened as it leaves the tunnel at the other end, where each batch of timber enters. In the modern Erith progressive dryer the air entering near the discharge end comes from below and descends at the end at which the timber is admitted, so that the circulation of air is rotary; a shaft permits the exit of excess of moist air. This system is especially valuable where large quantities of the same kind of timber of equal dimensions have to be seasoned.

The temperatures used vary from 70° F. up to nearly 232° F., according to different customs, and according to the purposes for which the wood is destined; the higher temperatures are especially used in seasoning softwoods (coniferous timbers).

It may be noted that experiments have been made on seasoning with rarefied air, but do not appear to have resulted in the evolution of any commercial kiln.

The account of seasoning of timber would be incomplete without mention of certain preparatory treatments sometimes adopted as a preliminary to either natural or artificial seasoning.

Timber is sometimes soaked or stored for a long time in water. This washes out some of the constituents, and therefore renders the timber less hygroscopic. It tends, therefore, to cause it to shrink slightly more, but swells slightly less than is normally the case.

Sometimes timber is soaked in salt water or treated with hygroscopic salts, such as commercial magnesium sulphate, or with a saccharine solution. Treatment with hygroscopic salts tends to reduce shrinkage but increase swelling.

In one process of soaking with saccharine solution, known as Powellizing, heat is the agent employed to induce penetration of the sugar.

In so-called "senilization" of wood solution of magnesium sulphate or other substances are caused to enter by continuous or alternating electric currents.

It is conceivable that the soaking with hygroscopic substances renders it possible to employ more rapid methods of drying without deleterious results; but this has not been demonstrated.

Discussion

Mr. Legros (Past-President)

said the lecture was very instructive, and explained a number of the phenomena met with in wood which had always been difficult to understand thoroughly.

The drying of timber without destroying the strength had always been a big problem. It was thought at one time that spokes of gun carriages could only be seasoned by being kept about forty years in stock, and oak and ash for railway carriages were also kept in stock for many years. The same applied to wood used in agricultural implements. In England forests were now being cut down, but the wood was mostly only fit for pitwood and box-making. The subjejct raised by the lecturer would become even more important later on than it was at present. People were now making such things as gramophone boxes out of the scraps from aeroplane works, and a big price was being obtained for such small timber, as it was well seasoned and workable.

Woodwork formed a large percentage of the industrial work of this country, and after the war it would be important that the wood-working industries should be supplied with satisfactory material.

Lieut. A. P. Thurston, R.F.C.,

said the aeroplane was a most highly developed engineering structure, and timber formed its most important constituent, and therefore they could not know too much about the properties of timber.

Having had some little responsibility in connection with aeroplane design, he had often had to search records and make experiments to obtain such information, but what he knew he did not intend to say. He had found the reports of the Forestry Division of the United States of the greatest use. It was time this country had a corresponding service, and he would like to suggest that Professor Groom should have a responsible position in that service. He would like to ask Professor Groom to prepare a table giving information as to compressive and tensile strength, the modulus of elasticity, shear strength—radial, tangential, and transverse—of timber, taken from the same tree and subjected to natural seasoning and to the various artificial processes. This was wanted urgently if designs were to be drawn scientifically. He would also like to know what was the effect of the drying on the shear strength, radial, tangential, and longitudinal. The effect as regarded compression and tension was well known. He would also like to know of a good process of seasoning.

Dr. Kernot

said it was stated that there was a difference between wood artificially seasoned and that naturally seasoned. He believed there was a difference in the mechanical properties, but he did not know whether Professor Groom meant only the mechanical properties but also other properties. He (Dr. Kernot) did not think the seasoning of wood meant only the elimination of water. The seasoning ought to be looked upon also as a chemical transformation of the substance of the wood. In natural drying there was the action of the oxygen of the atmosphere together with the ultra-violet rays, and the action of bacteria, which probably caused the transformation of the carbon hydrates contained in the wood, and also probably the destruction of some of them and the formation of new ones. The formation of new compounds and the elimination or destruction of others had a lot to do with the mechanical properties of the wood. Probably if the natural drying could be imitated an improvement on the present artificial systems would be obtained. Carpenters and experts in wood preferred not to use artificially seasoned spruce because, they said, it had no lag, and he believed that was connected with the chemical transformation of the substance of the wood. He believed that researches had been started in America from the chemical point of view, and he thought they should start the same kind of work here, and they all looked to men like Professor Groom to be guides in that research. He believed Professor Groom already had the idea of starting that work. In England woods selected without any knowledge had been used for dry distillation. We had some kinds which were excellent for the production of acetic acid and therefore for the production of acetone, which was important at present. Other woods gave a large amount of methyl alcohol and no acetic acid. So far as he knew, at present no distinction was made between the two woods, and they were distilled together without any selection. If there were a laboratory in which the chemical changes in the natural seasoning could be ascertained an improvement could be made in the artificial seasoning, which at present consisted only of the elimination of water.

Capt. Kennedy, R.F.C.,

said he was pleased to learn that artificial seasoning produced a satisfactory product, as it would be essential for the supply of material in the future.

Capt. Bishop, R.F.C.,

said he thought something more than mere drying was necessary. He once witnessed a process of "cooking" the wood prior to drying, and the amount of foreign matter that came out of a balk of timber was amazing.

Mr. Powell

said Professor Groom was an eminent botanist and knew all about the life and structure of timber and vegetable products, but he (Mr. Powell) did not think a botanist was the ideal man for knowing how timber might be seasoned. Timber, in the first place, was strengthened by the introduction of sap, introduced by nature into the plant, but how timber could be stregthened by evaporating the water he failed to understand, and they had not been told that in the lecture. Most people in England only wanted facts and did not care how they were produced. If they got suitable wood by an artificial process they did not want months of inquiry in a laboratory to show why it was produced.

Mr. Howard

emphatically disagreed with Mr. Powell. He, as a man with nearly 40 years' experience of observation, buying, selling and distribution of timber, was astonished to hear any man suggest that the scientific inquirer had not benefited the practical man. It was the want of such scientific instruction from which England had been suffering He knew of a case where a theoretical student made a discovery which chemists had been seeking for more than a quarter of a century. The objejct of the process of desiccation was not to make timber stronger, but to render it useful in a much shorter time than would be possible by natural seasoning, and to leave it no less strong as the result of the seasoning, if possible. The more light that could be thrown on the subject the better it would be. One wanted to know the qualities of the various timbers and treat them accordingly.

Mr. A. E. Berriman

asked whether artificial seasoning was a proved proposition technically on a commercial scale. Could wood be seasoned artificially in commercial qualities with assured success—he meant rather in a financial sense? The objejct of that question was to obtain an answer to a further for large timber users and dealers to put down question, whether it was to-day a national duty

THE FOKKER TRIPLANE*

IT has been one of the features of the development of German aeroplanes during the war that, up till comparatively recently, their performance has been obtained by a constant increase in engine power rather than by highly efficient aerodynamical design. Such refinements as stream-lined cables, and "spinners" over the propeller boss were not in the past a characteristic feature of German aeroplanes. As, however, the demands for better and still better performance grew, the Germans were obliged to pay more attention to such details, and such machines as the Albatros chaser, with its stream-line semi-monocoque body, was one of the manifestations of this attempt at increased efficiency. The Fokker triplane marks a further step in the battle against that enemy of efficiency, Kx, once expressed by Mr. A. E. Berriman, we believe, as the price paid for the lift. In the Fokker triplane this price has been reduced to what would appear to be an irreducible minimum. So far has the designer gone in his reduction of head resistance as to eliminate all trace of external lift bracing. The Fokker triplane can, therefore, be said to be of the "wireless" type; more truly so than is the case with, for instance, the Curtiss "wireless" in which, although no wires are employed, the struts sloping out from the landing wheels to the lower plane perform the function of lift wires.

No such struts are fitted on the Fokker triplane, the internal construction of the wings being designed to provide all the strength without any external aid of any kind. The interplane struts, which are really ties rather than struts, might conceivably have been omitted altogether, and so far as one is able to judge, their only function is to help to distribute the load more evenly between the three wings. It is well known that in a biplane the upper wing carries about four-sevenths of the total load (when the wings are of equal section, span, and chord) and the lower wing about three-sevenths. In a triplane much the same distribution is found, with the exception that the middle and lower wing each take a share (not equal) of the three-sevenths of the total load.

In the Fokker triplane the upper wing is of larger span than the middle wing, which in turn is of slightly greater span than the lower wing. In consequence, as the three wings appear to be all of the same section, the upper wing must carry more than four-sevenths of the total load. In order to provide a better load distribution, the middle and lower wings are made to cary their share of the load on the top plane by connecting them to this *via* thin high fineness ratio strusts, which are in reality ties as they are working in tension. This explains why the struts are so extremely thin (about ½ in.) and the moment of inertia of the strut section would be so small that the struts would buckle under a very small load if subject to compression.

The fact that no lift bracing is employed naturally necessitates wing spars of considerable depth if the spar weight is to be kept reasonably low, and in the Fokker triplane this has been attained by making the wing section very thick in proportion to the chord. As a matter of fact the section is a far greater percentage of the chord than any we have ever seen on a modern aeroplane. For the time being we cannot go into details. This must be postponed until we do a full description of the Fokker, but roughly we should say that the maximum camber is in the neighborhood of one-eighth of the chord.

The two wing spars are placed very close together, and are enclosed in a box of three-ply wood. The function of this box is two-fold, it increases the strength of the spars for taking bending and at the same time acts as internal drift-bracing. At the moment of writing we are not able to say whether or not any other drift bracing is employed, but we are inclined to think that this function is performed solely by the ply-wood box.

The upper wing, which is in one piece, runs right across, and is supported on struts sloping outwards as in the Sopwiths. The other two wings each have a centre section rigidly attached to the body, the middle one resting on the top longerons and the bottom one running *underneath* the lower longerons, an aluminium shield streamlining the normal surface presented by the deep flat sides of this spar.

From the illustrations it will be seen that the gap is unusually small, being very considerably less than the chord. The inefficiency thus caused is partly made up for by staggering the wings but even so one would imagine the machine to be somewhat inefficient. The interference owing to too close spacing of the wings chiefly affects the lift co-efficient, and as the machine is probably very lightly loaded—compared with the majority of German machines—it is possible that the landing speed is not excessive.

Strictly speaking, the Fokker is not a triplane. It would be more correct to term it a three-and-a-half plane, as the wheel axle is enclosed in a casing of plywood which has a section somewhat similar to that of the wings. Experiments have shown that floats of such a section as to have a deeply cambered top surface may be made to support their own weight during flight. In the case of the Fokker triplane it appears probable that this ply-wood casing around the wheel axle carries a not inconsiderable load during flight. Its section appears capable of supporting a fair load per square foot of area, and its inefficiency due to low aspect ratio is probably less than one would expect in a plane of an aspect ratio of about two, on account of the proximity of the covered-in wheels to the tips, the effect of which must be to stop end losses to a considerable extent.

As regards the body of the Fokker triplane this is constructionally very similar to that of the Fokker monoplanes. Longerons as well as struts and cross members are in the form of steel tubes, and are joined together by welding. The internal bracing of the body is peculiar in that the bracing wires are in appearance in duplicate, although they are not so in effect.

The arrangement, to which we shall revert again when dealing with the Fokker in detail, does not appear to possess any other advantage than that in each bay only half the number of loops have to be made in the wires.

The tail plane, as well as the elevators and rudder, is made of steel, and is of a symmetrical section, much thinner than that of the Albatros, but otherwise similar to it in that no external bracing is employed. While this is quite satisfactory in the Albatros on account of the thick tail plane spars employed, it appears wholly inadequate in the Fokker, as the plane is very thin, and since, moreover, the trailing edge of the tail plane is a steel tube, which section, as is well known, is not a good one for a laterally loaded beam, owing to the fact that much of the material is massed around close to the neutral axis where it is not taking very much of the load.

As exhibited at the Enemy Aircraft View Rooms the Fokker is not complete inasmuch as the engine has been removed. The cowling shows without a doubt that the engine must have been a rotary, and the mounting is of the type usually employed for rotary engines, *i.e.*, a main engine plate bolted to the nose of the body, and a pyramid of steel tubes, supporting at its apex the rear end of the crank-shaft. A sheet of aluminium is place immediately in front of the engine plate. The manner of cowling in the engine will be apparent from our illustrations, and does not present anything of particular interest, following as it does conventional practice.

Although they are not in place in the machine as exhibited, it is evident from the aluminium casings for the cartridge belts that two synchronised machine guns have been fitted, one on each side above the fuselage. The usual triggers, operating the guns through Bowden cables, are mounted on the control lever, which latter is of the usual type.

Painted on the side of the fuselage are the following data relating to the weight of the machine: Weight empty, 376 kg., useful load, 195 kg., total weight, 571 kg. (about 1,250 lb.).

With these brief particulars we must leave the Fokker triplane for the time being, but later on we hope to return to it again, and to be able to give illustrations of some of its more important constructional details.

---

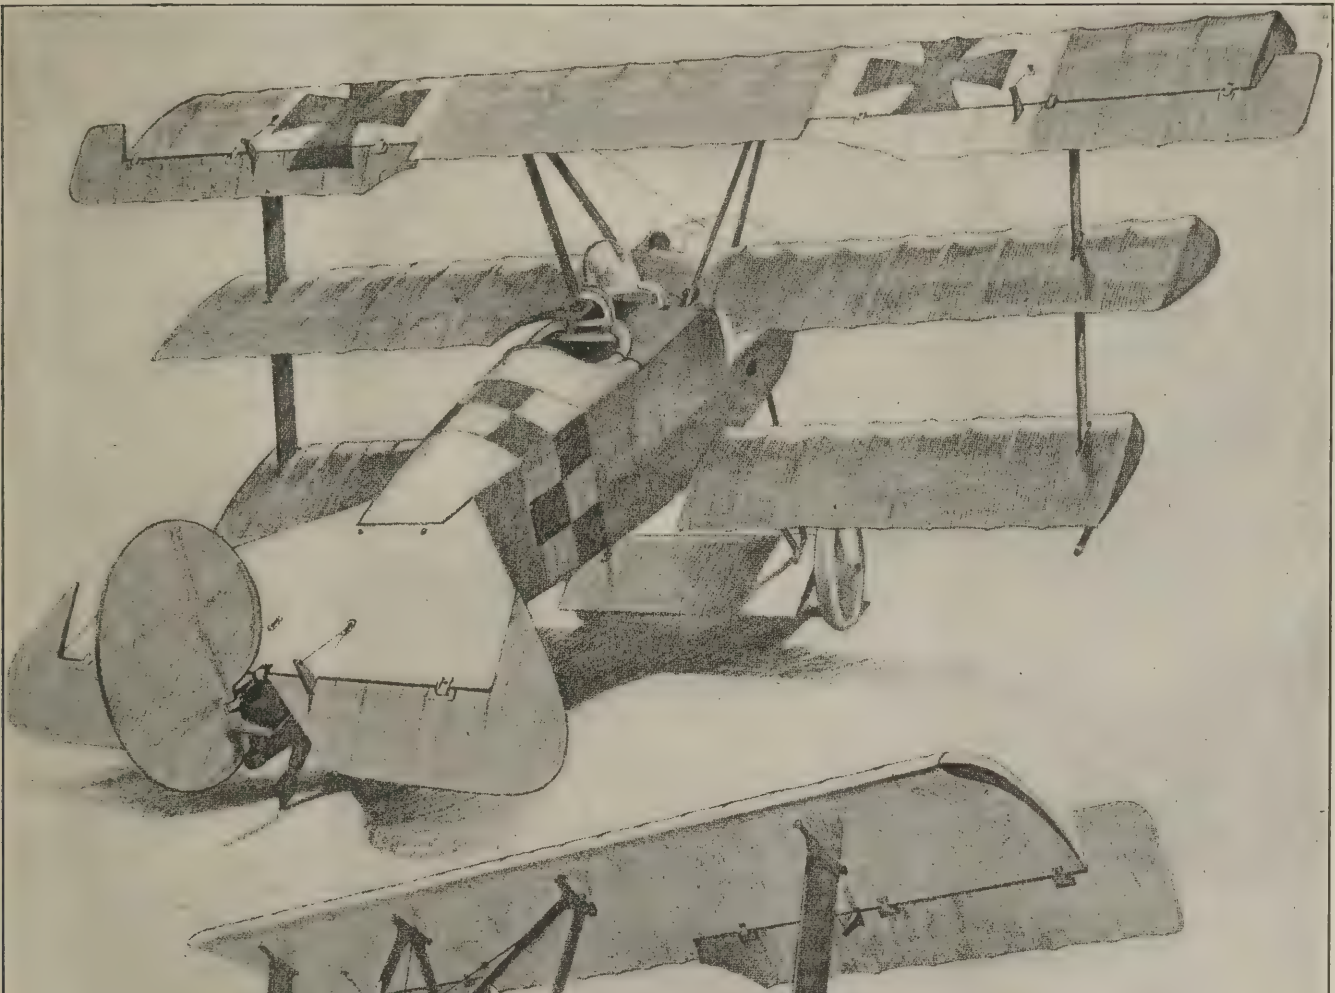
PERSPECTIVE SKETCHES OF THE GERMAN FOKKER TRIPLANE



The upper sketch shows a three-quarter rear view of the Fokker Triplane. This illustration gives a good idea of the general arrangement of this interesting machine. Note the small veneer plane enclosing the wheel axle. Below is a three-quarter front view of the Fokker Triplane. The thickness of the wings can be imagined from an inspection of this drawing. The pin-jointed struts are really ties rather than struts as they are working in tension.

FOREIGN NEWS

FRANCE

Reporting on aerial operations the announcement of April 10th says:

"It is confirmed that five additional aeroplanes have been brought down."

According to the day announcement of April 11th:

"On April 10 two German aeroplanes were brought down by the fire of French machine guns."

The night statement of April 11th reports:

"In the mouth of March twenty-eight German aeroplanes were brought down."

Extensive operations are described in the French announcement of April 12th:

"On April 11 our pursuit aeroplanes engaged in numerous combats, in the course of which two German aeroplanes and a captive balloon were brought down. Twelve other German machines were seriously damaged and fell within their own lines. The same day our escadrilles dropped 16,000 kilos of projectiles on the railway station at St. Quentin, depot and aviation grounds north of Montdidier. A violent fire destroyed hangars at Campien and an explosion was noted in the St. Quentin station. It is confirmed that an aeroplane and a captive balloon of the enemy were destroyed on March 23 and two aeroplanes on March 31."

The French official statement of air operations of April 13th says:

"On April 12 our aeroplanes displayed great activity along the whole front, particularly in the regions of the Somme and the Oise. Our pursuit machines carried out more than 350 sorties and fought 120 engagements. Eight enemy aeroplanes were brought down, 23 others fell within their own lines, seriously damaged; five enemy captive balloons were set on fire, five others, pierced by bullets, dropped precipitately to the earth.

"Our bombing machines likewise carried out demonstrations. In the day of April 12 and the night of April 12-13 a total of 48,000 kilos (nearly fifty-three tons) of projectiles were dropped in the course of these expeditions, in which Italian machines took part. The railway stations of Jussy, Roye, St. Quentin, Nesle, Ham, Guiscard and Noyon, railways, cantonments and numerous convoys in these regions, as well as the stations at Hirson, Laon and Montcornet, were copiously bombed. Several fires and explosions occurred."

German aëroplanes attempted a raid on the Paris district. The official statement on the raid issued April 13th states:

"German aeroplanes crossed the lines going south. Only two succeeded in flying over the Paris district, dropping a few bombs. The number of victims is not yet known."

Later reports state that eleven persons were killed in Paris and fifty injured.

French aviators have discovered the location of the big gun with which the Germans have been bombarding Paris at long range, and the continual bombardment of the spot by the French artillery and bombing by the airmen have made the handling of the piece difficult. This explains the intermittent fire of the long-range weapon.

The piece is mounted at Crepy-en-Laonnois, near the road from La Fere to Laon.

Le Matin learns that Flight-Sergeant Paoli, having succeeded in escaping from a German prisoners' camp, has arrived at the French frontier.

It is announced by the *Temps* that the Duc de Chevreuse has been killed as the result of a flying accident while training as an aviator.

GERMANY

"Capt. von Richthofen achieved his seventy-seventh and seventy-eighth aerial victories," says the official report of April 8th.

A summary of a month's activity is officially made on April 9th:

"The losses in March of enemy aerial fighting forces in the Western theatre amount to twenty-three captive balloons and 348 aeropalnes. Of the latter, 158 were brought down behind our lines. The others were observed to fall within the enemy's positions. We lost eighty-one aeroplanes and eleven captive balloons."

Combat activity is reported on April 11th by the German War Office:

"In aerial battles during the last few days thirty-seven enemy aeroplanes and three captive balloons were shot down. Lieut. Menckhof attained his twenty-fourth aerial victory."

The official communication on the recent air raid against England issued from Berlin on April 14th says:

"On Friday night Frigate Captain Strasser, with one of our marine airship squadrons, attacked important storage, manufacturing and shipping places connected with war industries in central England. Birmingham, Nottingham, Sheffield, Leeds, Hull and Grimsby were bombed.

"Despite the extraordinarily strong gunfire encountered and pursuit by airmen, all our airships returned safely."

Two of the "star" German pilots have recently been killed in action. Lieut. Buddecke, who has been killed on an Eastern front, had received the Order Pour le Merite, and was claimed to have brought down twelve enemy machines, while Captain Baron von Tutscheek, the victim of a French pilot, is credited with twenty-seven victories.

The Munich correspondent of the *Lokalanzeiger* says that the Bavarian airman, Max Muller, has been killed in an accident due to engine trouble He stood next to Baron von Richthofen in the number of victories claimed for him, namely, thirty-eight.

GREAT BRITAIN

An official statement on aerial operations April 10th says:

"During the morning the whole front was covered with a mist, which prevented any of our aeroplanes leaving the ground. Later in the day, when there was a slight improvement in the weather, our machines reconnoitred the new battlefront between La Bassée and Armentières and bombed and engaged with machine gunfire the enemy's attacking troops.

"Hostile low-flying machines also were active in this sector. Four of these machines were brought down by our aeroplanes, and one was shot down by our infantry. Two of our aeroplanes are missing."

The British War Office reports the following aerial activity on April 11th:

"The weather Wednesday was very unfavorable for flying, but as soon as it was possible to leave the ground our aeroplanes went out to reconnoitre the battelfront. Useful information was brought back as to the position of the enemy's troops, which were attacked with bombs and machine gun fire. Enemy low-flying machines also were active on this front. Three were shot down in our lines by intantry, four were brought down by our aeroplanes, and one was driven down out of control. Seven of ours are missing.

"At midday to-day we raided the Luxemburg station and over a ton of bombs were dropped. Several bursts were seen on and around the station. All our machines returned."

The following official statement on aerial operations was issued on April 13th:

"Atmospheric conditions were favorable Friday and a great concentration of our machines was effected on the battlefront. A large number of low-flying machines were employed in bombing and sweeping with machine gunfire roads packed with enemy troops. Thirty-six tons of bombs were dropped and more than 110,000 rounds of ammunition were fired.

"In the meantime other formations, flying at a greater height, engaged the enemy planes, which were extremely lively in this sector. *Forty German machines were brought down and twenty others were brought down out of control.* Two were brought down by gunfire. Twelve of ours are missing.

"Incessant bombing was carried out between dark and dawn. More than twenty-two tons were dropped on the Douai railway station and roads leading to the battle front in the neighborhood of Estaires."

An official statement on aerial operations April 14th says:

"On Saturday it was cloudy and misty, but our low-flying machines dropped 1,200 bombs on enemy troops on roads leading to the front. Only a few fights occurred and the results were indecisive. One of our machines is missing."

Five persons were killed and fifteen injured in a German air raid on England. The official announcement of April 12th follows:

"Four airships participated in last night's raid. Two of them penetrated a few miles inland. Of the other two one reached the midlands and the other nearly reached the northwest coast. The raiders were traveling at a great height and showed no inclination to attempt to penetrate defended areas.

"Most of the bombs were dropped in open country, and apart from the demolition of four houses at one place the damage so far reported is inconsiderable. Particulars of the casualties will be published later."

Perry Robinson, writing to the *Daily News* Monday sent the following despatch from British correspondents' headquarters on April 10th:

"Day before yesterday (Saturday) was a bad day in the air, when sixteen of our machines failed to return. We have had the same thing before during Flanders fighting on a somewhat similar scale. In the early part of the day the visibility was good and the air perfectly clear up to 4,000 feet and more. Then suddenly a mist came driving before a rising westerly wind, making the whole air dense down to within 400 feet of the ground.

"Losing their way and buffeting against wind which rose to a gale, our men came straggling in some hours after they were due, and sixteen did not come back at all that day. Only a few days before, however, when somewhat similar conditions occurred, out of thirteen who failed to return the first day, five afterwards came in, having landed at remote spots whence they could not communicate with their commands."

GREECE

The Greek Admiralty has authorized the employment of a woman seaplane pilot, Miss Demise Kalimeri, who is the daughter of one of the government aeroplane engineers.

ITALY

Several squadrons of Caproni aeroplanes are operating at the French front, being employed for bombing purposes, according to diplomatic advices received in Washington. The Italian aeroplanes were said to be doing effective work with both the British and French armies.

These machines are identical with the giant Caproni biplane which flew from New York to Washington and is spending a week co-operating with the Liberty Loan Committee in that city.

KOREA

The *Chinese World,* a San Francisco publication, received advices from Shanghai on March 25th, reporting that an aeroplane, believed to be a German machine on scout duty, had appeared over Korea.

What part of Korea the flier had been reported from was not disclosed in the telegram.

NORWAY

A fast aerial freight and passenger service is to be maintained between Norway and Scotland by hydroaeroplanes. Machines are being designed by Captain Gyth Dehle, who has had charge of the Norwegian Naval Hydroaeroplane Works. When in service it is estimated they will make the trip from Stavanger, Norway, to Aberdeen, Scotland, in less than five hours.

Norway's plan to obtain foodstuffs for her starving population in spite of the continued German U-boat campaign became known recently, when the report of United States Consul H. E. Carlson at Christiania, Norway, was made public.

A Scale Model of the Pomilio Aeroplane

BELOW are shown some photographs of a very real looking model aeroplane. It is interesting to compare the pictures of this model with photographs of the real machine, shown in the April 15th issue of AERIAL AGE. All the details have been correctly carried out in the model, and even the controls work in a realistic manner.

The engine cowling is of aluminum, and the body and surfaces are covered with aeroplane linen, doped and varnished to a high finish. A miniature machine gun is mounted at the rear, fixed so that the gunner's seat revolves with the gun ring to which the gun is attached.

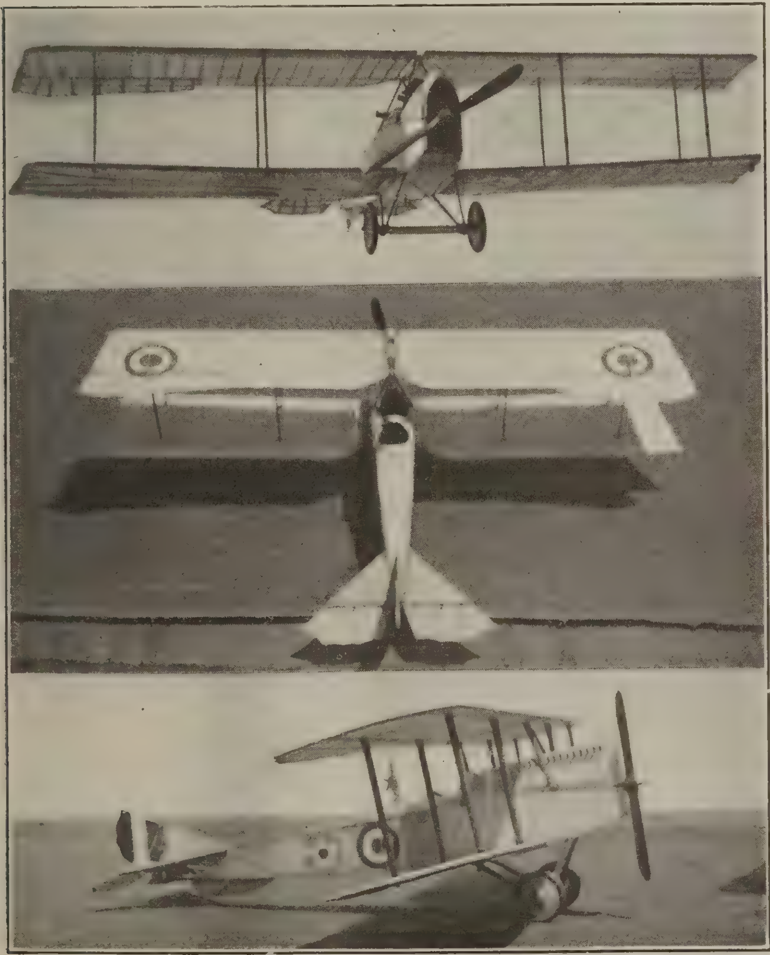
Dimensions of the Pomilio scale model are as follows: Overall length, 2′—8¼″. Span of both planes, 7¼″. The gap between the planes decreases from 7″ at the body to 6½″ at the wing tips. Overall height, 11½″.

Struts between the planes are located 9¼″ from the center-line of the body, and other struts 9½″ from middle struts; overhang 4½″. From front to rear the struts are spaced 4½″ apart.

The body is 2′—5½″ long, 4¼″ deep at the forward end, 5¼″ deep at the passenger's seat and 1½″ deep at the stern. It is 2″ wide at the radiator, 3¼″ wide at the passenger's seat, tapering to the stern.

The span of the tail plane is 10¼″; depth, 5″. Span of the elevator, 13″, depth 2¾″. The rudder is 5″ in height, overall. Wheels are 2¾″ in diameter and are spaced 6½″ apart. The axle is bound to the chassis by rubber bands.

The model bears the insignia of the United States Air Service—white star in a blue circle, with a red circle in the center—and the insignia of the Royal Italian Air Service—a red disc surrounded by rings of white and green.



A "true to scale" model of the Italian Pomilio Reconnaissance Aeroplane, built by a workman in the Pomilio Aeroplane Factory

Hollow Spars for Model Construction

F. J. Camm, in "Aeronautics" tells of some easy methods of making hollow tubes for model fuselage construction. One method is to wrap thin sheet spruce around a former of a length of circular section wood (a dowel stick), or metal tube, lapping and gluing the edges. A piece of brown paper must be folded around the former to prevent the glue from sticking the spar to it.

Another way of building up hollow tubes is to use a paper-covered former as before, and folding brown paper around this until a tube of suitable thickness is obtained. Each layer of paper would require to be coated with very thin glue. Although inclined to be heavy, great strength is possessed by such construction. In a flying model the tubes can be made to enclose rubber strands for driving a propeller, thus eliminating resistance which exists when the strands are exposed.

A method of making a hollow rectangular spar is to cut a deep groove in one side of a solid spar and then to glue a thin strip over the open side.

Another form of hollow spar is the H Section, which can be much improved by closing the channels with a silk tape binding. Strength is imparted to the spar by so wrapping. The same applies to the X section spar. If yellow Japanese silk tape is used for the binding and afterwards finished with two coats of varnish, the result is a spar that will be unaffected by dampness and of a rather pleasing appearance.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Don't Read Them—Sing Them

Tune: "My Old Kentucky Home."
I've got a sneaky feelin' round my heart that I want to bomb a town.
I guess I'll pack my grip and take a trip where I might drop somethin' down.
Now I'm helpin' in this war
I'll give Master Boche "what for!"
There's a lesson due to Essen,
I'll be tickled to death to know
That I can fly right there over Fritzy's happy home.
I guess I'll make a fuss on my Detroit 'bus
With my new Kentucky Gnome.

[*This does not necessarily mean that the Gnome motor is now being made in Kentucky. I put that in to mislead the Huns. Also because it rhymes.*]

Tune: "Way Down in Tennessee."
Way down in Tennessee
Just try to picture me
Doing my first v.p.—
It put the wind up me.
All I could do was keep hold, and forget what I'd been told,
My knees knocking something shocking,
Both my feet felt cold.
The roses round the door
Appealed to me no more,
I saw my stern C.O.
And friends I used to know,
And they were right there to meet me—
You should just have seen them greet me—
When I flew back—yes, I flew back
To my home in Tennessee.

[*Excuse my interrupting again for a moment, but I want to make it clear that I do not mean to indicate that a training depôt for Zepp.-strafers has been established in this well-known locality. One has to be so careful of these D. O. R. A. Regulations, and I should hate to give information to the enemy—unless I knew it was wrong.*]

Tune: "You'll Always Be the Same Sweet Baby."
You're my precious little Sopwith,
You are all the world to me,
You're the kind of 'bus to stop with.
(*N.B.—I could'nt avoid that rhyme.*)
And when the weather's warm and you feel in form
There's oh! oh! oceans of climb in you.
When the Huns are round about me
Life is not too full of glee,
But when my motor's dud and the Archies burst
'Till I get cold feet and an expensive thirst
You'll always be the same old Sopwith to me.

Tune: "The Long, Long Trail."
There's a long, long raid a-coming
Into the land of the Huns,
Where the Eau-de-C'logne is humming
And where Krupps make guns.
It's a long, long time we've waited,
And we've behaved far too well.
But now we're going to give those Germans
What Lloyd George called—"Hell!"

Tune: "Dixie."
I come from Dixie—I said from Dixie,
In the land of cotton I learned to fly.
To land in cotton is pretty rotten,
And I've often gotten cotton in my eye.
But flying to a rag-time tune is all the rage,
I take up lots of niggers in my Family-Page,
They sing with fervor, and my observer
He sings of Dixie too.

[*If I may butt in again for a second, I would like to draw particular attention to my new name for the Handley-Page. In view of its marvellous passenger-carrying records I think I've found a good one. But let the music proceed.*]

Tune: "Every Little While."
Every little while I hear an Archie,
Every little while a bit goes through.
My fabric's tearing—I can't help swearing,
The sky is bright blue, and I'm blue too.
(*With the cold and with funk, lor' love yer!*)
Every little while I think they've got me,
Every little while I hate their style,
(*Now I'd like to be home!*)
And while I keep on flying through it
I wish they wouldn't do it,
But they may keep missing all the while.

Tune: "When You're All Dressed Up."
When you're all dressed up and your motor won't go,
Life seems weary, dreary and slow,
You get an aching head and bad words are said
When you've nowhere to go, unless it's back in the shed.
And when your Flight-Commander comes on the field
To the spot where your big 'bus has been wheeled
And says, "Why—ain't you gone?" Your answer is "No!
I'm all dressed up, but the motor won't go."

Tune: "It's a Long, Long Way to My Home in Kentucky."
It's a long, long way to the middle of Potsdam,
Where the Kaiser hangs round the old palace door;
It's a long, long way, but when once we get started
With our T.N.T. we will give him "what for!"
So, weep no more, my Wilhelm,
Just push those beers away.
It's a long, long time we're been talking about it,
But we're bound to get there some day!

And, in conclusion, a sample verse and chorus from "The Broken Doll," as it might be sung by a pilot who has just returned from a flight over the lines, with a new gunner-observer, who looks pretty, but can't shoot for nuts:

I wonder why I always fly the way I do,
But now it seems that all my schemes go wrong through you.
I used to bring the Boches down in days gone by,
But all that now is changed somehow—I wonder why!

Chorus:

You climbed into my 'bus an hour ago,
I thought that you looked very nice to know;
You said you could shoot well—I thought you knew,
Though I've had dud observers long before I met you.
The Huns kept flying round us all the while,
But you missed every one by half a mile.
If that's your form today, I am sorry to say,
You're as useful as a Broken Doll!

Well, there are a few suggestions for you, and I hope they will inspire some budding song-writer to try and go one better—for I cheerfully admit it might be done. To the American Air Service I say, "Welcome to Europe! Have as merry a Christmas as you can. Sing while you have the chance, for there's heavy work ahead of you. We are counting on you to help to end this horrible war, and when it's over we'll sing rag-time and any old thing you like, however rotten the rhyming!"

Douglas W. Thorburn,

plant to meet what was an existing emergency. The objejct of these questions was to obtain a basis upon which to judge whether such plant would probably be profitable after the war. Was there any existing timber seasoning plant that was worthy of immediate use?

Mr. Clifford

said the lecture indicated that heavy woods were stronger than light ones. He would like to ask how Professor Groom would reconcile that with a condition that came to his (the speaker's) notice. He had to make some small wood parts the strength and weight of which were of vital importance. He took a piece out of a plank of ash and cut it into pieces of 1-in. section. It had perfectly straight grain, and he was informed by experts that it was a healthy looking piece of wood. When he tested the pieces the load they carried varied 100 per cent, and the fractures occurred in every direction. He did not know whether it was naturally or artificially seasoned.

Mr. Evans

asked whether the lecturer could give the results of seasoning in a vacuum and in high and normal temperatures.

Lieutenant-Colonel R. K. Bagnald-Wild

said some of those who had joined in the discussion appeared to be looking upon the matter primarily from the aeronautical side, and hardly realized what it meant from the automobile point of view. It was important that they should get busy quickly after the war, and artificial seasoning must be used. There was very little seasoned wood left at present.

Would Professor Groom state his experience as regarded close control of temperature in kilns? The A.I.D. had rejected a lot of wood, and the trouble was traced to lack of control of temperature. He thought a hydrometer was a necessary portion of the testing outfit. Were the speed of drying and the temperature control essential features in kiln drying? They wanted to know if a certain percentage of moisture went into the kiln what was the percentage when the wood left the kiln, and whether that percentage could be varied for different classes of work. Would it be safe to work on, say, 15 per cent for high-class work where wood was going to be stressed highly, and could the percentage be much more for less important work? Research should be encouraged in every way. Size varied with humidity. In the A.I.D. they had passed on wet days wood which had been rejected on dry days, but by the use of hydrometers they had defeated that ruse of the contractors. There was not going to be any scrap out of propellers, as they used the little bits glued together. A Paper giving hints as to the avoidance of waste would be valuable.

He proposed a hearty vote of thanks to Professor Groom, and it was carried unanimously.

Prof. Groom

replying to the discussion, said he did not think the problem mentioned by Dr. Thurston, as to the comparative results of drying by natural and the artificial processes had been satisfactorily settled. It was a complex question, though it sounded simple. The qualities of a piece of timber varied as one proceeded outwards from the centre and also as one proceeded upwards from the bottom to the top of the tree, so it was difficult to get exactly comparable parts of the tree.

With regard to the effect of dryness on the shearing strength of the wood, if one gradually dried a piece of wood, the co-efficient of elasticity and, above all, the compression strength, and to a considerable extent the elastic limit and the bending strength, were inversely proportional to the amount of water content. The curve was linear in relation to moisture contents at various strengths, but so far as he knew no exhaustive work had been done in regard to the shearing strength in different directions. The Sturtevant and the Chamber processes were certainly satisfactory when carried out under A.I.D. inspection with autographic recorders of the temperature and humidity, and there were other satisfactory kiln processes in which the same automatic records could be used, such as the improved spray kiln, invented by the Forestry Service of the United States, which anyone could use. Excellent work was being done by the Erith kiln, and no doubt others were also satisfactory.

He thought his remark about the seasoning process being one of mere drying was rather misinterpreted. He meant the actual operation, and not the scientific explanation. It was known that many chemical changes took place. Prolonged humidity, high temperature, or prolonged steaming caused a color change. Broadly speaking, artificial seasoning had been proved over and over again to be a commercial success, so long as it was only desired to season the wood to stand well, and there was no doubt that for certain specific purposes it was a commercial success. He could not, however, answer the question whether in the future in this country woods could be seasoned so that they would be mechanically uninjured, though it was certainly a commercial success now. The extensive programme of national reconstruction would in itself largely fill the kilns of this country. The mechanical effects of the artificial process would have to be nearly as good as those of the natural process. His own impression was that the answers to both Mr. Berriman's questions were in the affirmative.

With regard to Mr. Clifford's mysterious piece of ash, ash had not been exhaustively investigated in this country. The most competent timber leader in existence, he believed, was Dr. Jancke, an Austrian, and he had written an exhaustive paper on the strength of ash from the point of view of its use in sheaves, and he gave formulæ for calculating its strength.

In reply to Mr. Evans, seasoning in vacuo had been attempted at low atmospheric pressures, and it had not been a commercial success. At every phase of the seasoning there must be a proper regulation of temperature or a moisture in the air. The statistics he had given showed the extent to which the temperature could be raised. In America he believed much higher temperatures were used than were used here. The temperature and rate had to be determined for various classes of wood by experiment. On a commercial scale he believed wood was seasoned down to six per cent of moisture. Wood dried to that extent would have to rise to its proper equilibrium, and it would absorb moisture. In a dry place it might only rise to eight per cent, but the average would be perhaps from 13 to 17 per cent. For outside work in wood that had to be varnished the figure should be about 13 to 17 per cent, but for an object that was moving swiftly the value sank much below that.

THRIFT STAMP DAY IN THE U. S. A.

By W. WARD SMITH, Vice Chairman Pioneer Division W. S. S.

JUST as it takes over 2,000 parts to make an aeroplane, so it takes many contributions to make up the fund to pay for winning the war.

May 6th, 1918, will be known and observed throughout the United States as Thrift Stamp Day. On that day, every store, shop, stand, booth, counter and individual in the land selling goods of any character at retail will urge every customer to accept one or more 25-cent Thrift Stamps as part of his or her change on every purchase. This, of course, applies to purchases where the amount of money handed to the clerk involves the return of 25 cents or more in change. Where the customer's change would be less than 25 cents, the clerk, before accepting the customer's money, should ask the customer if he or she will include a 25-cent Thrift Stamp in the purchase. In this way the customer will be induced to hand the clerk another quarter for a Thrift Stamp.

The Two Incentives—Patriotism and Thrift

It is appropriate that Thrift should be combined with Patriotism as twin incentives to the success of Thrift Stamp Day. Of course Patriotism should be the main incentive on the part of American business, to dispose of as many millions of Thrift Stamps as possible on May 6th; on the part of the American public, to take as many millions of Thrift Stamps as possible on that day and furnish the U. S. Government with the sinews of war needed for Victory.

But Thrift will prove an extra incentive of vital importance to the overwhelming success of Thrift Stamp Day. From the standpoint of business the Thrift incentive is this:—"Thrift Stamp Day should boom business in general throughout the country. The greater the volume of business we do on that day the more Thrift Stamps we will sell for Uncle Sam. Here is one war 'drive' that should prove a tremendous boost to the business of every manufacturer, wholesaler, jobber and retailer in the land. Therefore we will strive to make Thrift Stamp Day, May 6th, 1918, the Biggest Business Day in the History of America! We will hold Special Thrift sales of every description and offer the most unusual values in every kind of merchandise and commodity on Thrift Stamp Day, May 6th, 1918, in order to encourage the public to do a record volume of buying on that day."

From the standpoint of the American public the Thrift incentive is this:—"We will take advantage of the Special Thrift Sales and extraordinary values offered on Thrift Stamp Day to make as many purchases as possible on that day and supply all our needs for food, clothing, housefurnishings, etc.—merchandise and commodities of every description. The money we actually save through economical buying on Thrift Stamp Day will go a long way to balance the amount we invest in Thrift Stamps on that day."

The Time Is Short—Get Busy

May 6th is only a few days off. Every W. S. S. worker, every business man in the country, should try to accomplish a day's work in every hour that remains. Remember, we are all working to help Uncle Sam, to help business, to help ourselves. Let's put Thrift Stamp Day over big, and we'll make everybody happy.

If you can only grasp the immensity of this Thrift Stamp Day idea we know that your own enthusiasm will be aroused and you will communicate it to everyone associated with you in business. Never before has the whole nation set aside a day like this for doing a record-breaking day's business in every line of commodity selling at retail! It practically amounts to Uncle Sam turning shopkeeper for a day with every retailer in the United States as his partner and one hundred million Americans for customers! The possibilities for such a day's business are almost limitless.

When business closes on Thrift Stamp Day, May 6th, 1918, every retail establishment in the land, from the largest department store in the largest city to the smallest shop in the village, should have completed the biggest day's business in all their experience, and the United States Government should have added many millions of dollars to its War and Victory Chest from the sale of Thrift Stamps!

CABINET MEMBERS APPEAL TO ALL TRUE AMERICANS TO SUPPORT WITH THEIR DOLLARS OUR GALLANT FIGHTERS IN THE FIELD

SECRETARY McADOO—Treasury Department

One million eight hundred thousand of America's brave sone are now serving in the Army and Navy of the United States. Thousands of them are already upon the battle fields of France, fighting and dying to save the liberties and rights of those who stay at home and to secure democracy and freedom against Prussian brutality and military despotism. Their blood already consecrates the soil of noble France.

Who can think of their heroic sacrifice without emotion?

Who can contemplate their trials and sufferings, their dangers and struggles without setting ablaze the fires of patriotism in his soul?

Who can look upon the blue jacket of the sailor or the khaki jacket of the soldier without admiration for the indomitable hearts that beat beneath—hearts that may soon be stilled in death as the price they pay to save civilization?

We must support our gallant sailors and soldiers. We must make them swift victors in their fight with the Kaiser. We can do it if we, at home, do our duty with the same quality of patriotism that animates our men in the trenches. The least duty we can perform—and we should be eager and happy to perform it—is to lend our money, every available dollar we have or can save, to our Government in order that our gallant sons may be supplied with all they need to save America.

JOSEPHUS DANIELS—Secretary of the Navy

On this anniversary of our entrance into the war the magnitude of our task and the tremendous responsibility which rests upon America comes home to us as never before. The progress of the war has demonstrated the inexorable determination of the German war lords to impose their cruel will not only upon Europe, but upon all the civilized world, and this menace will not be overcome unless we pour out our men and our money and our every resource. With all we have and all we are fully enlisted, the victory is assured. Until the German military autocracy is crushed forever there will be no safety in the world for any of the things America holds dear. Our men in the trenches and on the ships are counting their lives as nothing and are maintaining the highest standards of American manhood and heroism. It is our privilege at home to sacrifice and sacrifice and sacrifice to provide the Government with means to carry on the war. No man who values his freedom and loves the principles upon which our Government was established can afford not to contribute to the limit to the third Liberty loan. We must buy bonds until it hurts and then buy more.

ROBERT LANSING—Secretary of State

The United States has been at war for a year. The first enthusiasm which followed the declaration that we would take up arms in the cause of liberty and justice has passed, but in its place there has come to the Nation a spirit of determination and self-sacrifice. Under the influence of this spirit the Republic is pressing forward to the accomplishment of the mighty task which this was has imposed upon it.

Already the American people have responded generously and fervently to their country's call, but their efforts must not slacken. Again they are called upon to supply the Government with the needed sinews of war, even to the extent of personal sacrifice. Let there be the same patriotic response to the third Liberty loan that was made to those which preceded it. Let this response bear witness to the unswerving loyalty of the Nation and to the intense devotion of Americans to their country's cause.

T. W. GREGORY— Attorney General

The hordes of Satan are in battle against us. They fight with every diabolical device that perverted human intelligence, training, and experience can invent. To conquer us, they use to the full their every economic, scientific, and industrial resource.

To save the lives and liberties of ourselves and our children, we have been forced unwillingly to take up arms. To prevail we must dedicate to the farthest limit our every power. No sacrifice has been too great for our enemy to place on the altar of his fatherland. Shall we give or sacrifice less for freedom than our enemy gives for despotism? What shall a hoarded penny profit us if we may spend it only as slaves? Let us give freely, that we may live free.

W. B. WILSON—Secretary of Labor

The Third Liberty Loan has an even greater significance than the first two. They were the expression of instant and responsive patriotism. This serves a grim notice on the foe that America is in the fight until the lives of its people are safe from the assaults of barbarism, its institutions secure against the attacks of autocracy, and the nations of the earth, including our own, are assured the opportunity of living their own lives undisturbed by the power of militarism. The Third Liberty Loan will, likewise, be a trumpet note of inspiration to all the brave peoples fighting with us that back of them is an inexhaustible Nation which under Providence will be their sure help and reliance. The Third Liberty Loan is in a way the first in which, unmistakably, we tell the world that America is steadfast in the battle and enlisted for the war.

A. S. BURLESON—Postmaster General

One year ago we took up the gage of battle flung in our faces by Germany. It is a righteous war, waged by our people. No more inspiring exhibition of patriotism was ever made than the response by them to the requests of President Wilson that they contribute to its support by purchasing our Government's obligations. To the inexhaustible magazines of their patriotism, their fidelity, and valor the appeal is made. He knows us not who doubts that the response will be far beyond the amount required. Upon patriotic Americans every reliance can be placed. They will prove true.

DAVID F. HOUSTON—Secretary of Agriculture

The first anniversary of the entrance of the United States into the world conflict finds the people of the Nation united in the great struggle against Prussian domination and determined to prosecute it to a victorious conclusion. The Nation's task is a serious one. It intimately touches each of us. It faces you and me. If we do not win this war we shall indefinitely face the interference of the Prussian autocracy or bear permanently the intolerable burdens of militarism. To win this war we must have both men and money. It is the duty and privilege, therefore, of every citizen who is in a position to do so to participate in the third Liberty loan campaign. He will thereby contribute directly and effectively to the successful prosecution of the war which Germany has forced upon us.

BENEDICT CROWELL—Acting Secretary of War

We are now at war with the greatest military organization that the world has ever known. Soon we shall be locked in a death grapple with this monster of militarism. It is a fight to a finish with an enemy that gives no quarter to the vanquished.

We realize the enormous task before us and we are confident of winning, but it will take the combined punch of the whole American people and will require an immense expenditure of men and money.

Did it ever occur to you to think what would happen if we failed? If we are beaten in France the struggle will probably be transferred to American soil. Plans for the invasion and subjugation of the United States are now on file in the office of the German general staff. This we know definitely. This invasion will mean that we are to suffer here all the horrors of Belgium and Poland. Mr. Reader, do you wish your wife and children to be actors in such a drama of frightfulness?

I am appealing for the success of the Liberty bond issue. It is a matter which directly affects every man in the United States. I strongly urge you to buy all the Liberty bonds that you can afford, and then a few more. There is no better investment for you on earth. Remember that the Germans issue no bonds for the money they extort from conquered peoples.

THE AIRCRAFT ADMINISTRATOR BILL

ON April 15, Congressman Gould introduced the following bill, which was referred to the Committee on Military Affairs:

A BILL; To provide for an Aircraft Administrator, and for other purposes.

Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That there is hereby created the office of Aircraft Administrator, to be in charge of an Aircraft Aministrator, who shall be appointed by the President, by and with the advice and consent of the Senate, and who shall receive a salary at the rate of $7,500 per annum.

There shall be in such office a Vice Aircraft Administrator, who shall be appointed by the President, by and with the advice and consent of the Senate, and who shall receive a salary at the rate of $5,000 per annum, to have charge of the approval of all contracts and of all funds under such rules as the Aircraft Administrator may prescribe.

There shall be in such office four assistant administrators, each of whom shall be appointed by the President, by and with the advice and consent of the Senate, and shall receive a salary at the rate of $4,500 per annum. One of the assistant administrators shall have charge of research and experimentation division as directed by the administrator. One assistant administrator shall have charge of an engineering and design division to supervise engines and planes and approve of accessories such as ordnance, radio apparatus, cameras, instruments, and so forth, which may be needed. One assistant administrator shall have charge of a production division and the requisitioning of all material, including accessories required for the product, and of a purchasing section under his jurisdiction which shall cooperate with the War Industries Board. One assistant administrator shall have charge of a distribution division which will include a traffic department to direct the movement of all purchased goods or completed product.

The Aircraft Administrator shall have full authority to lease, purchase, or construct all necessary office space or office equipment for the conduct of the business of this office. There shall also be in such office such experts, attorneys, clerks, and other employees as may be necessary, and as may be from time to time provided for by Congress.

SEC. 2. That it shall be the province and duty of the Aircraft Administrator to encourage aircraft production and to develop the science of flying, and he shall be vested with full control over the governmental activities dealing with aeronautics.

There are hereby transferred to the office of the Aircraft Administrator the Aeronautic Section of the Signal Corps of the War Department and the office of Naval Aeronautics of the Navy Department, together with all that pertains thereto, and the President shall, from time to time, as he thinks best, transfer to the office of Aircraft Administrator the whole or any part of any bureau, division, or other branch of the Government engaged in work pertaining to aeronautics, and shall assign to such office any military or naval officers or enlisted man that he may deem necessary. All unexpended balances of appropriations available for the use of any transferred bureau, division, or other branch of the Government, or which may become available thereafter, shall be available for the office of Aircraft Administrator.

SEC. 3. That there is hereby appropriated, out of any money in the Treasury not otherwise appropriated, the sum of $25,000,000 to be available immediately, for the office of Aircraft Administrator for the purpose of carrying out the provisions of this Act.

The Aircraft Production Board is hereby abolished, and the unexpended appropriations, if any, available for such board is hereby made available for the Office of Aircraft Administrator.

THE NEWS OF THE WEEK

Tardieu Reappointed French Mission Head

Washington.—Captain Andre Tardieu has been reappointed High Commissioner of France to the United States for the third successive term. News of his reappointment met with expressions of approval from officials of the State Department, the War Board, War Industries Board and Food Administration this afternoon.

Daniels, in Seaplane, Flies Over the Capital

Washington.—Secretary Daniels was a passenger with Lieutenant Doherty, a naval aviator, in a twenty-minute flight over the capital.

A service hydro-aeroplane was used.

At the American Aviation Training Camps

In order to provide more room for the Army Aeronautical School at the Massachusetts Institute of Technology, the regular classes in the department of civil engineering have been transferred to the faculty room in the Administration Building.

Chanute Field's aviators will soon be soaring over Rantoul as of old. The week-end saw the arrival of a large shipment of aeroplanes. Twenty-five flying cadets, just graduated from ground schools, have also arrived on the field, and with 250 more to come from ground schools all over the United States, the flying season will be in full swing very soon. The weather will play an important part in how soon flying will start. The field is in good shape, the majority of machines have been set up, and the flying students are also ready for their initial trips. Captain Harry M. Smith will be in charge of the flying field and hopes to have not less than fifty machines in constant commission all summer. The soldiers spent the greater part of last Sunday unloading the large shipment of planes which arrived on Saturday.

When the Flying Cadets at the University of Illinois marched in the Liberty Bond parade, they were led by a band of their own. Already four hundred and fifty dollars have been raised to make the organization of a band possible. Until now, the Flying Cadets have been forced to be content with the music which the buglers and drummers provided at retreat every evening. But within a short time the squadron, as they pass in review, will march to the lively tune of "Joan of Arc" or "Over There," played by the Aviation School Band.

Major John Purroy Mitchel had probably the most thrilling experience of his career at North Island, when he took up trick flying work. With Lieutenant Robert Mairesse, of the French Flying Corps. Major Mitchel executed a full loop, half loop, tail spin, sideslip and the Immelmann turn.

Bosch Company Taken Over By Government

Washington.—The Bosch Magneto Company of Plainfield, N. J., and Springfield, Mass., with property valued at $5,000,000, was taken over by Alien Property Custodian Palmer. Investigation revealed that instead of most of the stock being owned by residents of this country, as had been reported by its officers, ownership was in reality vested in Robert Bosch and other residents of Germany.

Carl L. Schurz of New York, whose father fled from Germany after the revolution of 1848 and became a United States Senator, now is president of the Bosch company, and he and Gustav Jahn are the directors. Bosch, who an investigation conducted by Mr. Palmer has shown is the real owner of a majority of the stock, has been in Germany since the war started.

According to evidence gathered by Francis P. Garvan, director of the Bureau of Investigation, the conduct of the company after the European war started and before this country entered the war was such as to indicate plainly its German ownership. The company, according to a statement issued, refused to take orders from the Allies, and after the United States entered the war it apparently was loath to render any service to this Government in its war preparations.

The Bosch company was largely manned by Germans and when this country declared war its president was Otto Heins. At that time Heins and many of the Germans who were heads of departments walked out of the factory and clearly showed their purpose to be to tie up the business so that it could not be used in making war on Germany. The company manufactures magnetos for aeroplanes, automobiles, trucks and other army and navy equipment.

Bolling and Miller, Reported Missing, Confirmed as Killed

Colonel Raynal C. Bolling, formerly chief counsel for the U. S. Steel Corporation, who was reported as missing in these columns last week, has, according to information received from Germany, been killed.

Captain Miller, who was last seen in combat over the German lines and was listed as "killed in action," fell in battle with two German aeroplanes, according to information obtained by Swiss officials.

Lieut. Patton, Veteran Aviator, Heads British Royal Air Force Recruiting in U. S.

Lieut. Colonel G. Francis Patton, son of the present Duke of Wellington and great-grandson of the Iron Duke, hero of Waterloo, has taken command of the Royal Air Force in New York and will push the work recruiting. Lieutenant Colonel Patton started flying in 1913 and joined the Royal Flying Corps in 1914, before the beginning of the war. He was one of the first aviators to go to France, and fought at Mons, Soissons, Marne and Aisne. Later he served in Egypt.

Mineola Proposed as Aerial Terminal

Springfield, Mass.—Details were announced here of a plan backed by the Chamber of Commerce that will be submitted to the War Departments for a triangular training course for student aviators with Mineola, L. I., Springfield and Boston as landing points.

The plan originated with M. W. Rose, a vice-president of the Springfield Aircraft Corporation, and would locate hangars on the field that is being used for trial flights here.

French Sky Fighters Presented With Auto Truck

In order to facilitate the transportation of the Official Aerial Warfare Exhibit, which is being sent throughout the United States for the benefit of the French Sky Fighter's Fund, a motor truck was presented by Mr. S. O. Ochs, a member of the Aero Club of America, on which the entire exhibit can be loaded. The truck was build as an ambulance for the Russian Government, but owing to chaotic conditions existing in that country, it was not sent there.

New War Dirigible Exhibited to Senators

Washington.—Demonstrations of a 16-foot model dirigible of the Zeppelin type swung on wires—a machine said to be much superior to the German craft in that it is more mobile and can alight on water—were given to the Senate Military Committee by Alfred Herbert, a Montclair, N. J., inventor. He said his dirigible could be built 600 feet in length, carry fifty persons, machine guns, and bombs, and attain a speed of seventy-five miles an hour.

Development of the dirigible by the Government was urged by the inventor, who said Germany in time would send Zeppelins to America.

New Wright-Martin Plant

To take care of the new government orders for 400-horsepower Hispano-Suiza aviation engines, the Wright-Martin Aircraft Corporation is arranging for the construction of a new plant. It is understood that sites at Philadelphia, Poughkeepsie and one near Atlantic City are under consideration. In connection with this contract, which has been definitely placed, the Wright-Martin Company will in the next few days enter the market for 500 machine tools, costing upward of $4,000,000.

2,000 Foot Drop is Art Smith's Art

Art Smith, the famous exhibition flier, who made eighteen successive loops at the Pan-American Exposition, is living up to his reputation for recklessness. At one of the western fields, he went up on a windy day when none of the pilots would go up, and proceeded to loop the loop fourteen times. On another occasion he flew a speedy little triplane, which no one had dared try out He rose to a height of 2,000 feet, when the machine was seen to drop down perpendicularly. The ambulance was rushed out, but Art had fooled them. All he wanted was some spark plugs and a mechanic, for just before striking the ground, he had straightened out and made a perfect landing.

Free Aeroplane Wing Covering and Repairing Course in New York School

A course in aeroplane wing covering and repairing will be started at the Murray Hill Evening Trade School, 237 East 37th Street, New York City. Three sessions weekly will be held from 7:30 to 9:30. Tailors, cobblers, awning makers, and upholsterers are eligible to enter this class. The instruction is absolutely free.

Martin Aeroplane Plant Nearly Ready

Cleveland.—The 5-acre plant being built for the Glenn L. Martin Aeroplane Co. is rapidly approaching completion, and it is expected that the Martin company will be in production in about 60 days.

The formation of this company marked the entrance into the aeroplane industry of a concern which not only intends to build war products, but which will probably be an important factor in the commercial aeroplane post-war developments.

The company is incorporated for $2,000,000 and has erected its plant on a 55-acre field, which is sufficient not only to give plenty of room for expansion but also to allow a landing and experimental field for the planes manufactured. Only in a few instances have aeroplane factories been able to obtain flying accommodations in close proximity to the plant.

Navy Asks Huge Aero Wood Supply Monthly

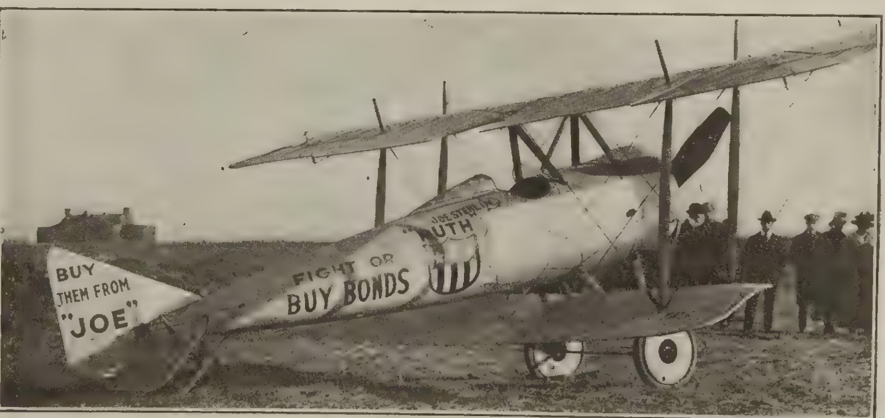
Boston.—A call for three million feet of New England spruce a month for aeroplanes was sent out by the Navy Department.

By an agreement with the army, the navy has been given the exclusive control of the development of the New England spruce. Steps already have been taken to bring the output of this material up to its maximum.

Variable Pitch Steel Aero Propeller Wanted

Washington.—A steel air propeller combining a variable pitch is sought by the National Advisory Committee on Aeronautics and the committee invites the attention of designing engineers to the problem.

The first requisite is a propeller that will fill the need for a super-charging engine, one which will enable an engine to maintain constant power at all altitudes. All aeroplane engines now in use lose power as they attain higher altitudes. When the air density is, for example, 50 per cent of the density at the



(Photo passed by Censor)

The Berckmans speed scout which is completely described on page 348.

ground, the engine loses 50 per cent of its power and is forced to double speed to attain the normal horsepower achieved at ground density.

The second requisite is that the propeller be steel, because it is believed that this will be the ultimate material for propellers. The committee advocates that designing engineers try to find the solution to both problems at one time.

Engineers of the committee offer the suggestion that the variable pitch can be controlled either by a governor, if one can be developed to alter the pitch without changing the engine's speed, or by a device at the driver's seat. They advise engineers in designing this steel propeller not to pay any attention to the wooden ones now used. They point out that when steel bridges were first made the engineers attempted to follow the design of wooden bridges and failed until they evolved new designs based upon steel strength and structure. An ideal variable pitch propeller would be one that embodies the means for changing simultaneously the diameter, area and pitch for changes in air density.

All designs will be given careful attention, and drawings should be submitted together with brief description and necessary photographs to the National Advisory Committee for Aeronautics, Munsey Building, Washington, D. C.

Col. Howard to Teach Military Science at Columbia University

Washington.—Lieut.-Col. John Howard, retired, has been detailed by the War Department as professor of military science and tactics at Columbia University, New York City.

New Aeronautic Companies Organizing in Increasing Numbers

The Milwaukee Woodcraft Corporation, Milwaukee, Wisconsin, has been incorporated with a capital stock of $25,000 by representatives of the wood-working industries of that city, to handle prospective contracts for wooden aeroplane parts and material now in negotiation. The incorporators are Marshall C. Moss, J. W. Dierckmeier, and S. H. Grobben.

The British Aeroplane Varnish Co., Union, N. J., has commenced the erection of the first of seven buildings on a property recently acquired from the Holzapfel American Composition Company and will devote a large portion of the plant to the manufacture of a special aircraft varnish. The works will cost about $30,000.

The Aero Instrument Corporation, New York, recently incorporated with a capital of $500,000, has leased property at 310 Hudson St., for a works. Initial operations will be devoted to the manufacture of altimeters for the Government. N. W. Walker and J. W. Lovell are the incorporators.

The Standard Gas Engine Co., Oakland, Cal., has completed plans and specifications for increasing its foundry capacity to double its present output. This is in addition to the recently announced additon to its main factory building and machine shop, work upon which is about completed.

The Tandem Aeroplane Co. of America, New York, has been incorporated with a capital of $100,000 to manufacture aeroplanes. The incorporators are F. Lawrence, C. Baas and F. Wallberg, 500 W. 40th St., New York.

British Air Force Announces Policy

An explanatory pamphlet has been issued by the Air Council of Great Britain wherein are set forth the rank, grading and pay of members of the new Air Force. From a careful analysis of the language of this official statement one gathers that any officer holding a commission in His Majesty's service may be transferred to the Air Force, subject to his own consent being given, except in the case of the Royal Naval Volunteer Service, which consists of reservists of the Naval Air Service, and the Royal Flying Corps, who, should they withold their consent, cannot receive a commission in any other branch of the services. The period is for four years of service, or for the duration of the war—whichever be the longer.

Promotion, so the pamplet runs, above the rank of lieutenant, will be by selection and not by seniority.

Personal Pars

E. M. Elliott, formerly manager, Department of Labor, U. S. Public Service Reserve, Washington, is now assistant factory manager, Wright-Martin Aircraft Corporation, New Brunswick, N. J.

Lieut. Col. Charles Lee, British aviator, who has been in this country for some months and who, with Lieut. Sully, also of the British flying corps, made many hair-raising flights over Washington recently, kept a luncheon engagement at the Chevy Chase Club, flying from Philadelphia in a few minutes more than one hour and landing on the fair green in front of the west terrace.

In making his landing Col. Lee broke up several foursomes, the golfers scattering in every direction when the plane swooped down on them. In landing the machine threw a tire of one of the small landing wheels, but this was replaced in a few minutes.

Col. Lee and his mechanician, who accompanied him in the flight from Philadelphia, proceeded to the city shortly before 6 o'clock, landing on the flying field at Potomac Park after doing a few aerial stunts.

Lieutenant Joseph Stehlin, the American ace from the Lafayette Escadrille, is to fly in an effort to set a new altitude record for the Liberty Loan.

More than 15,000 persons crowded the Empire racetrack, at Yonkers, to catch a glimpse of Stehlin.

Civilians Can Now Get Licenses to Fly

Washington.—The Joint Army and Navy Board of Aeronautic Cognizance, which has the power to grant licenses to civilians desiring to operate aeroplanes over the United States, its territorial waters and other possessions, which was forbidden by presidential proclamation on February 28th, has announced that applicants should give the name of the operator, the machine to be used, names of passengers to be carried, identifying markings on the machine and other details to assure the military and naval forces as to the identity of the aircraft. All communications should be addressed to the office of the Board, at 1607 H Street, N. W., Washington, D. C.

Governor Edge of New Jersey addressing the employees of the Standard Aircraft Company

Aerial Mail Schedule Announced

New York.—The aerial mail service between Washington and New York, which the Post Office Department will inaugurate on May 15th, will operate on the following schedule: Leave New York, Belmont Field, Long Island, at 11:30 A. M., arriving at Washington at 3:30 P. M., with stop, midway, at Philadelphia. The Washington to New York service will operate on the same schedule.

Letters should be mailed from New York so as to reach Pennsylvania Station Post Office before 11 o'clock in the morning, so as to be delivered in Washington in the course of the same afternoon.

Michigan State Auto School Begins Aero Mechanics' Course

Detroit.—The Michigan State Auto School has opened an aeroplane mechanics' course in order to train the men needed for the aircraft industry and for the Signal Corps. The course extends over a period of two months, and includes assembly, repair and operation of aero motors. Curtiss parts as well as a complete Curtiss J. N. 4 machine are used in the instruction.

French Congress of Civil Engineers Considers Aeronautic Problems

Paris.—The French Congress of Civil Engineers was recently inaugurated in Paris in the presence of President Poincare, for the purpose of considering important after-war problems. The aviation section of the congress listened to an address by Lieut.-Colonel G. Espitallier dealing with the possibilities of aviation after the war, and the conclusions that the Ministry of the Colonies should organize an aerial geographical and photographic section and that a regular aerial post should be established over all the colonial routes at present by caravans only. A postal service was recommended for mail and parcel post over the important routes of France, as well as between France and Corsica, Alveria and England.

The Congress being of the opinion that aerial services could not succeed unless there was some guarantee against competition, was voted that aerial police regulation should be drawn up and that concessions should be granted to aeronautic traffic corporations, with a view of preventing damaging competition.

A resolution was adopted asking manufacturers to study big load capacity and high powered aeroplanes suitable for after-war commercial conditions.

Colonel Roche urged the organization of a scientific and technical staff for the aeronautic industry and State encouragement of every organization created with the object of training aviation engineers.

R. Soreau presented a strong case in favor of constructing a low-pressure and low-temperature laboratory-tunnel for testing aeroplane motors. He pointed out that the Germans have made great progress because they have such experimental equipment. A tunnel, to cost $300,000, 492 feet long, having two concentric chambers, the inner one with a diameter of 16.4 feet and the outer with a diameter of 24.6 feet was proposed. The object of the outer cylinder is to provide a return passage for the cold air of the central chamber, thus increasing the length of time during which this air could be cooled.

U. S. Tin Prices to Be Fixed

Washington.—The War Industries Board has been in conference with manufacturers, with a view to fixing the price of tin. This product has doubled in price since the beginning of the war. Tin is now being imported from Batavia, American West Indies, Dutch East Indies, Strait Settlements and China, but the tremendous needs of the war require careful conservation of the supply.

War Industries Board Fixes Spruce Price

Washington.—Representatives of the spruce industry and the War Industries Board have agreed on the following scale of prices for spruce: On random lengths, range from $35 to $48 a thousand; on lengths from 8 to 20 ft. from $40 to $55, according to size; for every 2 feet over 20, in length, an additional charge of $1 a thousand will be made. These prices will remain in effect until July 1.

Senate Still Taking Aircraft Testimony

Washington.—Frank G. Diffin, chairman of the International Aircraft Standardization Board, who recently returned from a conference in London, and William B. Stout, technical adviser of the Aircraft Board, testified before the Senate Military Affairs Committee, in secret session.

The Inter-Allied Conference on Aircraft Standardization

At the Inter-Allied Conference on aircraft standardization, more especially in regard to materials, arranged by the British Engineering Standards Committee, was recently held in London at the Institution of Civil Engineers. The delegates were welcomed officially by Mr. Churchill, Minister of Munitions.

Sir Maurice Fitzmaurice, vice-chairman of the committee, welcomed the delegates, and explained that the standardization of the components of aircraft and aircraft engines was being carried out by the committee as a war measure for the Department of Aircraft Production of the Ministry of Munitions.

Mr. Churchill said that the thanks of all were due to the committee for having taken over this very important sphere of action, and for having relieved the Technical Department of the Ministry of Munitions of a heavy and important branch of what would otherwise have been their work. He thought that very little had in reality been lost, and in some respects much had been gained, by not entering on a general scheme of standardization until sufficient experience had been accumulated to enable such standardization to reach its maximum effect.

A too rigid standardization in the early stages of development undoubtedly tended to hamper progress and design.

Alluding to the gloomy views taken by some people regarding the war, he said that he felt that such people could have no real knowledge or appreciation of the importance and power of aircraft. German resources were incomparably less than those of the Allies, who had the whole world to draw on, and by developing these resources remorselessly it was certainly within the Allies' power to dictate a military decision to their opponents.

Mr. F. G. Diffin, chairman of the American Commission, stated that the United States were wholeheartedly in this war, as Allies and friends, with the sole desire of attaining the best possible results for the common good. He agreed that standardization could be better effected today on the knowledge of what had passed than if it had been instituted earlier, and remarked that the only way to absolute success was through complete unity of action. The work was of tremendous importance, and he firmly believed that, if the fundamentals were kept well to the fore, most effective results could undoubtedly be achieved.

Colonel Dorand, chief of the French delegation, and Deputy Giuseppi Grassi, of the Italian delegation, expressed their Governments' desire most cordially to co-operate in the work of standardization, which was fully recognized to be of the greatest value to production.

Sir William Weir, Director-General of Aircraft Production, said that he had come to the conclusion that the best results would be achieved by carrying out standardization under the direct responsibility of the Engineering Standards Committee, as that body possessed a wealth of experience in the domain of standardization generally. In particular, he had been influenced by the fact that the Committee, in all its work, had associated itself with the manufacturers and suppliers intimately concerned with the production of the material in question, and that it was able to obtain a realization of the possibilities of what could actually be done during the war—which was the most important thing at the moment. He felt sure that the conference would be of the highest value to the aircraft programme of the Allies generally.

Sir Henry Fowler, K.B.E., Assistant Director-General of Aircraft Production, and chairman of the sectional committee of the Engineering Standards Committee immediately concerned in carrying out the work of aircraft standardization in Great Britain, presided over the technical sessions, which were attended by the delegates and by a large number of officers of the departments of the Air Ministry interested in the details of the subjects discussed.

It has been decided to recommend that permanent authoritative committees be instituted in Great Britain, Canada, France, Italy, and the United States, in order to maintain continuity of action and to carry forward in the most efficient manner possible the work of co-ordination, the Engineering Standards Committee, for the time being, acting as the distributing centre of this permanent international organization. It was suggested that the Committees should be constituted as folows:

France.—M. le Colonel Dorand (Inspecteur-Général des Etudes et Expériences techniques), Captain Etevé, Captain Pierron, Lieutenant Boislevé.

Italy.—M. le Commandant Benza, Chef des Services, de la Provisionnement de l'Aviation Italienne, Député G. Grassi, and Lt. A. Bonomi.

United States of America.—Mr. F. G. Diffin, chairman of the Aircraft Standards Board of the American Aircraft Board; Dr. W. F. Durand, Lt.-Comdr. D. Briscoe, Mr. Coker F. Clarkson, Mr. E. H. Ehrman, Mr. Charles M. Manly, Mr. James Hartness, Dr. A. L. Colby, Mr. F. G. Ericson, Capt. A. Tilt, Dr. F. R. Baxter, Lt. L. Selden.

Great Britain.—Sir Henry Fowler, K.B.E., Comdr. H. Anstey, Mr. A. E. Berriman, O.B.E., Mr. P. C. Cooper, Lt.-Col. M. O'Gorman, C.B., Dr. H. S. Hele-Shaw, Brig. Gen. Sir Capel Holden, K.C.B., R.A., Comdr. C. F. Jenkin, M.B.E., R.N.V.R., Capt. G. W. C. Kaye, R.E., Mr. C. C. Paterson, O.B.E., Mr. A. A. Remington, Capt. A. A. Ross, Lt.-Comdr. E. S. Saunders, R.N.V.R., Capt. T. Worswick.

Flax Production Department for Great Britain

The closing of Russian ports and increased demand for flax for aircraft fabric has prompted the British Government to organize a Flax Production Department on the Board of Agriculture. It is intended to get 10,000 acres of crop sown in the coming spring, so as to insure an adequate supply for the year, and to provide seed for the requirements of the following year. Yorkshire, Lincolnshire, Somerset and Fife, many years ago were important centres of an extensive flax production, and it is probable that a substantial revival of that industry will now be effected. The government is to pay $41 per ton for the total crop of seed and straw, and as a fair yield is from two to three tons per acre, and the seed for sowing is to be supplied free, hence the production of flax ought to be a very profitable investment for the British farmers.

Mitchel Goggles Report Denied

Major John Purroy Mitchel did not make any report, official or voluntary, about defects in goggles in use by aviators of the United States, according to Capt. Martin H. Ray, executive officer and official censor of the aviation station at San Diego. A report to that effect emanated from San Diego recently and was widely published throughout the country.

In a letter sent out by Capt. Ray to correct the impression and to warn against some "unaccountable" source of news concerning the activity of Major Mitchel, Capt. Ray indicates that steps have already been taken for proper control of the origin of news at the camp.

Capt. Ray's letter is as follows:

"As executive officer and also official censor of the aviation station at San Diego, I have received numerous letters concerning this article. Major John Purroy Mitchel has also received numerous letters of the same character, which he has turned over to me.

"Your article was evidently based on a news dispatch dated San Diego, March 21, as other articles apparently based on the same message have appeared in other newspapers of the country. We beg to advise you that the statements made in this dispatch are entirely unfounded. Since Major Mitchel's entry into the military service, he has never been a member of any board authorized to investigate aviators' goggles, and he has never voluntarily made any report concerning goggles. In addition to this, he has never offered any suggestion concerning defective goggles. The entire story is fiction to such an extent that we are unable to account for it in any way, except that since Major Mitchel's arrival here, he has been written up as responsible for numerous things which have never taken place.

"We will thank you for correcting the impression given by the article referred to above, and trust that we will soon be able to control the system which has resulted in your unintentionally being led to publish an article no one element of which has any foundation except that Major Mitchel is stationed at San Diego."

Musicale to Aid American Aviators

Prominent society women of the National Aeronautic Committee of the Woman's Naval Service, of which Mrs. Charles A. Van Rensselear is chairman, will hold a musicale in the ballroom of the Hotel Plaza on Wednesday evening, May 1. The proceeds will be used to provide athletic outfits for the young American aviators on the western front, including baseballs, bats, masks, and footballs.

Miss Florence Doane of 18 West Thirty-fourth Street is receiving applications for tickets.

Mrs. Francis McN. Bacon, Mrs. J. Stewart Barney, Mrs. Henry P. Davison, Mrs. E. H. Harriman, Mrs. Walter E. Maynard, Mrs. Paul Morton, and Mrs. William J. Schieffelin are among the patronesses.

With Our Boys "Over There"

Since all the American forces have been placed at the disposition of General Foch, writes E. Percy Noel for the N Y. *Globe,* there has developed a great change of atmosphere in the region occupied by the Americans, which is called the intermediate zone. This is true of all the services. The word "front" is frequently repeated, but the effect of the change of policy is most noticeable on the air service. The acceleration of aviation effort is so marked that the change to activity from the condition of things a few weeks ago may be comparable to an automobile which, after running with the brakes on, is suddenly released to free movement.

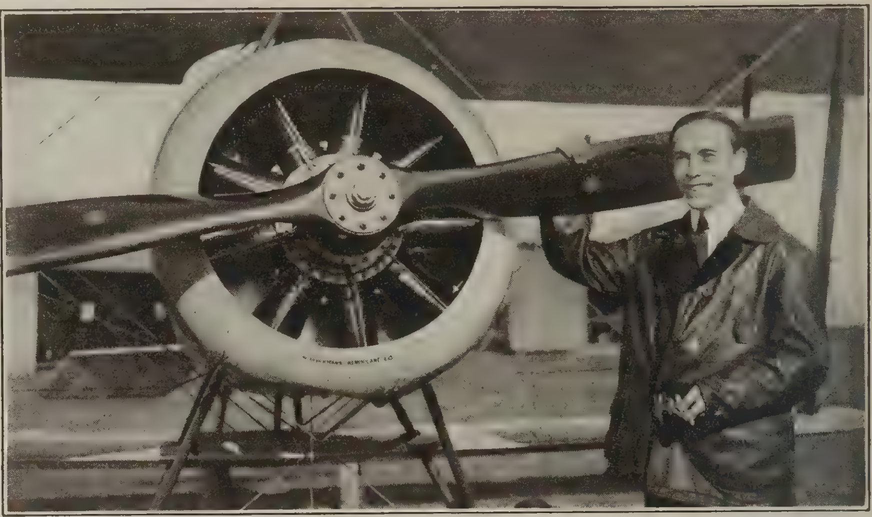
"Planes, not plans, results instead of progress," was the keynote. There and elsewhere, according to the object of the center, I found the same spirit. At an aviation industrial center which eventually will be America's largest establishment in France, great buildings of steel and corrupgated iron, had arisen Aladdin-like during the week. In one of them barely completed were tools and forges on the cindered floors. Here I heard a staff officer saying, "Our few hundred planes are on the way now and you will have to take care of them."

Returning from a reconnaissance flight, the aviator hands his films to the photographer for immediate development. (British Official Photo)

THE BERCKMANS SPEED SCOUT

By
GEORGE F. McLAUGHLIN

Description passed by the Committee on Public Information.

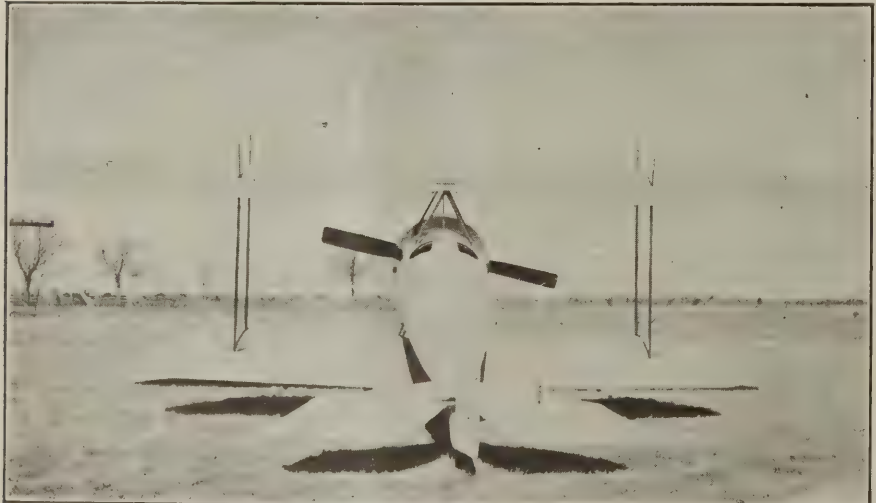


IN a great number of points, the little single-seater, designed by Maurice Berckmans, shows a marked advance in scout-building which has resulted in some performances worthy of note. In December the scout piloted by Bert Acosta ascended to 22,000 feet and returned to the earth in twenty-seven minutes. Its normal climb is 1,100 feet per minute. These figures were verified by an altimeter (indicating barometer) and two recording barographs.

Quick climbing ability is but one of the inherent features of its design. The streamline monocoque body, the reduction of exposed parts and the light total weight have assisted in the achievement of high speed. A judicious distribution of weights and areas, bringing the centers of erea, thrust, gravity and resistance in advantageous positions, has made the machine easy to control and prompt and precise in response to control movements. These attributes, together with its neat details and finish, easily distinguish the Berckmans Aeroplane Company's scout as one of the finest American machines of this type.

General Specifications

Span, upper plane	26'- 0"
Span, lower plane	19'- 0"
Chord, both planes	4'-11"
Gap	5'- 3"
Stagger	17°
Length of machine overall	18'- 0"
Heighth of machine overall	8'- 9"
Net Weight—machine empty	820 lbs.
Gross weight—machine and load	1,190 lbs.
Useful load	370 lbs.
Engine, G. V. Gnome	100 H.P.
Speed range	115-54 mph.
Climbing speed	1,100 ft. per min.
Gliding angle	8 to 1
Radius of action	2½ hrs.



REAR VIEW OF THE BERCKMANS SCOUT
Even at this close range the camouflage painting on this machine renders it semi-invisible
(Photo passed by the Censor)

Main Planes

The upper plane is in two sections with a 1° dihedral; lower plane in two 9'-6" sections with a 2° dihedral. Angle of incidence of both upper and lower planes, 2.1°; 1.5 at tips. Stagger, 17°, ammounting to 16 inches. No sweepback.

Area of the upper plane, 10.6 sq. ft.; lower plane, 77.9 sq. ft. Total supporting surface, 184.5 sq. ft. Loading, or weight carried per square foot of supporting surface, 6.4 pounds.

Wing curve, Eiffel No. 32. Ribs have ½" by 3/16" spruce battens and veneer webs. Veneer is with 3-ply birch-gum-birch, each lamination 1/16" thick. Ribs spaced along the wing 10" apart.

Leading edge and the forward main wing beam are of spruce, and the rear beam of ash (the ash being necessary because of the relatively narrow depth of the Eiffel wing section at the rear spar). The trailing edge of 20 gage aluminum tubing with an outside diameter of ⅜".

Ailerons on the upper plane only, 4'-10" in span and 1'-11" deep. The half-round leading edge is set into a curved recess in the rear wing beam, leaving no opening between these surfaces.

Interplane struts are of spruce, hollowed for lightness. The halves are glued together with fibre crossed (for avoiding warping) and bound in three places to keep them firmly in place. Maximum width, 1¼"; maximum depth (at the center), 4", tapering to 1½" at the ends. The front edge is nearly straight and the rear curved in a pronounced gradual taper.

Wiring between the planes is with flexible stranded cable; flying wires doubled and bound together to lessen resistance. The compensating control cable, from one aileron to the other, is run concealed in the upper plane. Inspection doors are located above the pulleys, where the cable ends emerge and run to the aileron king-posts.

Body

The fuselage is of the monocoque type, with a finely tapered streamline form. Its section at all points is perfectly circular; at the forward end it is 3'-0" in diameter. It is built up of 3-ply spruce, except the portion from the pilot's seat to the engine, which is 4-ply. Laminations are 1/16" thick, with coarse 1/16" mesh fabric interposed to keep the glue from shearing.

A headrest and streamline former is built onto the fuselage top aft of the cockpit.

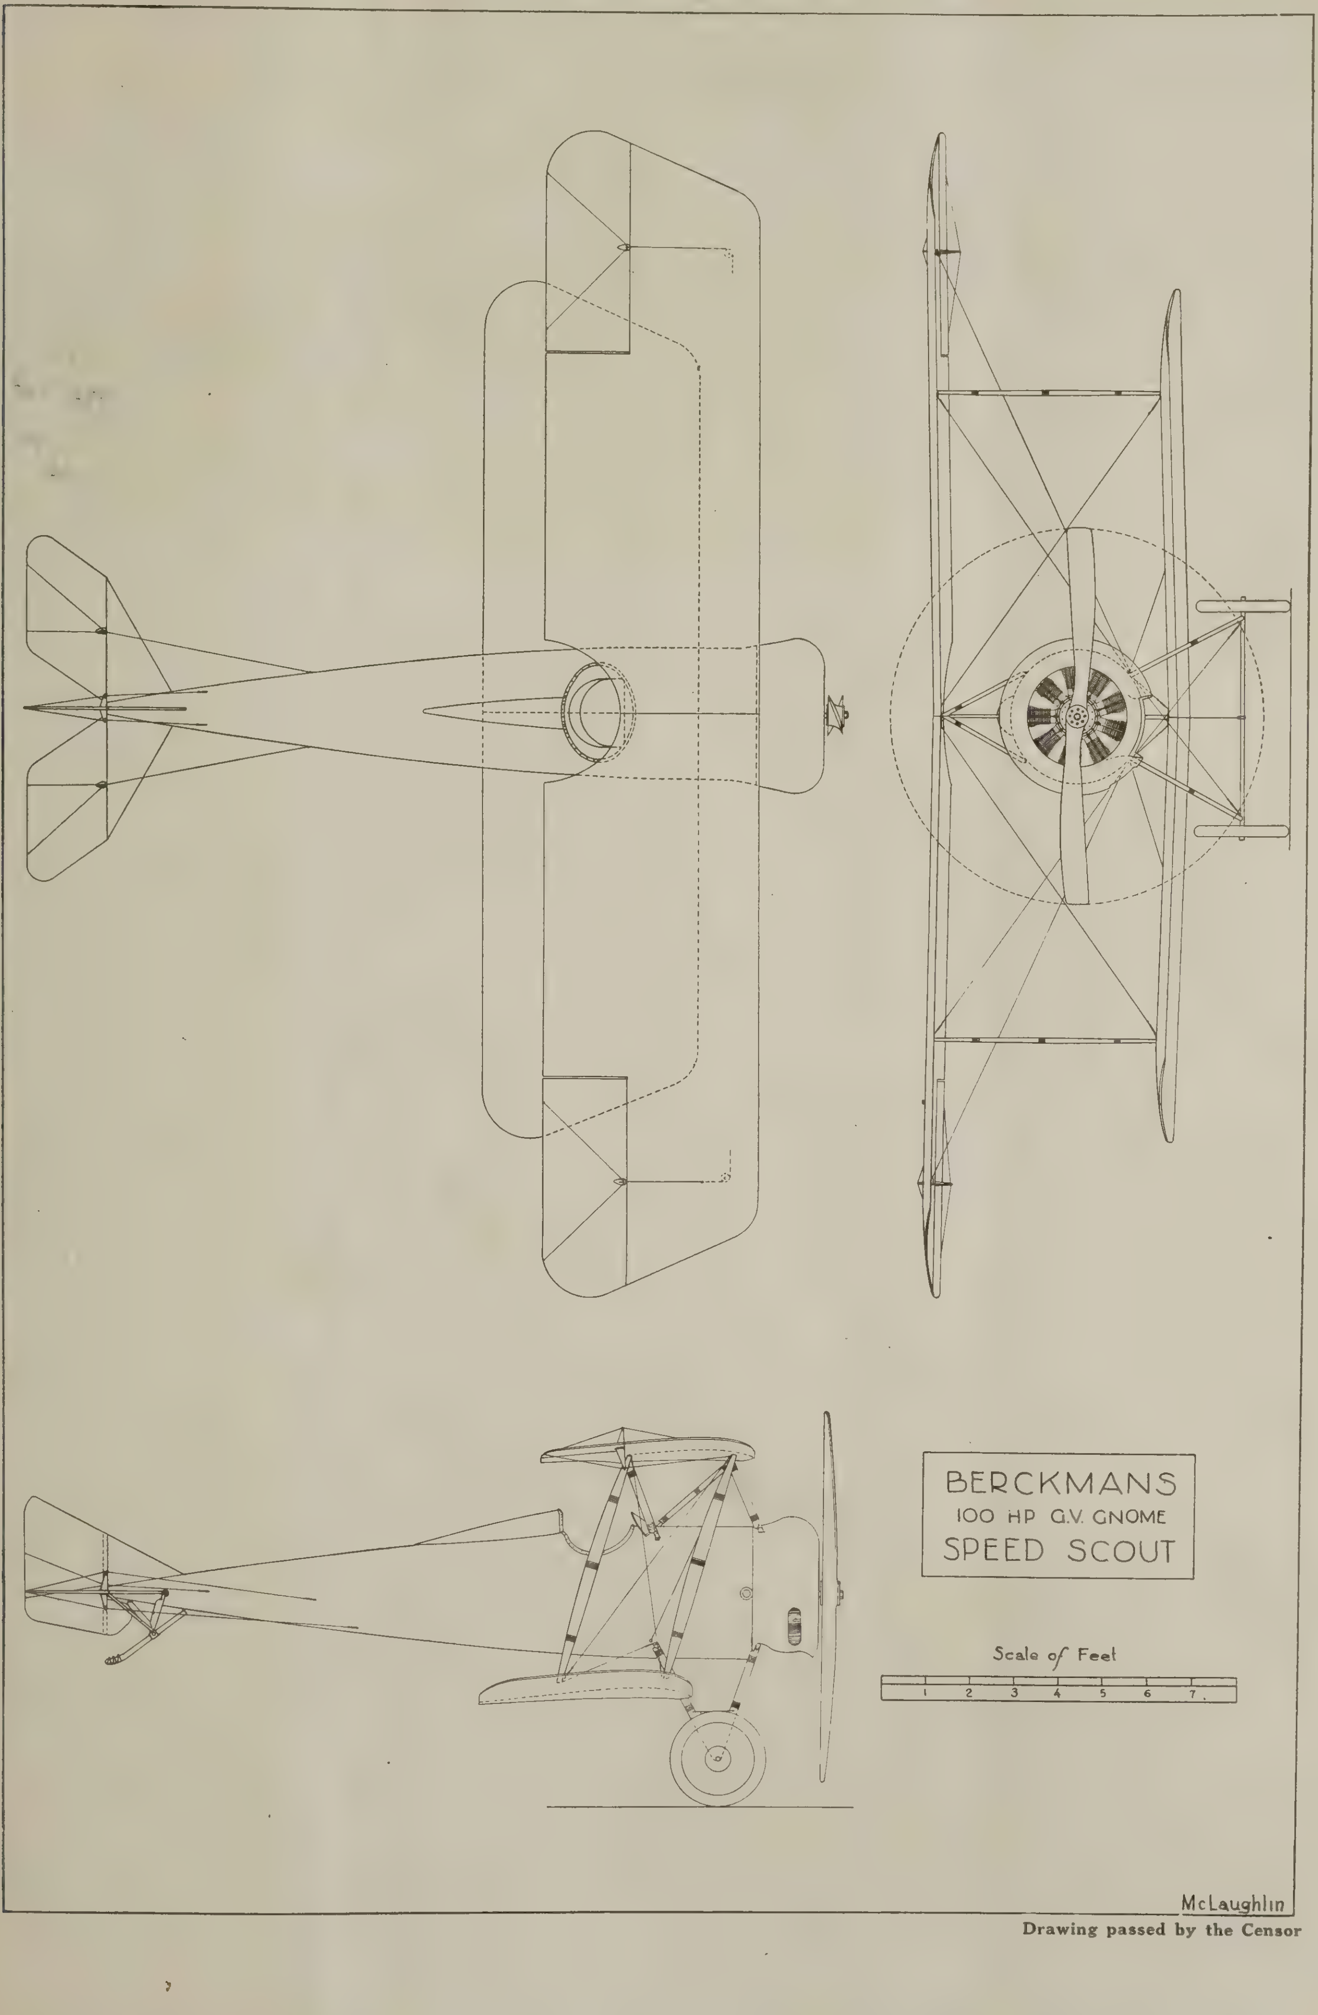
At the points where landing-gear struts and interplane flying cables are attached, the body is braced with rings of 1/16" thick U channel steel, riveted to the interior wall.

Stick control is installed; the stick for longitudinal and lateral movements, and the foot-bar for direction.

Tail Group

Light-gage Shelby steel tubing is used in the empennage construction.

(*Continued on page* 350)



Drawing passed by the Censor

(*Continued from page* 348)

The fixed tail-plane is set at a neutral angle. It is in two halves, attached to either side of the body. Overall span, 5′-9″; maximum depth, 1′-6″; area, 8 sq. ft.

Tail flaps have a span of 7′-9″ and a depth of 1′-9″; area, 9.5 sq. ft. They are recessed into the tail plane so as to leave no space between the surfaces.

The triangular vertical fin is 1′-9″ long and 1′-3″ high. Area, 2.5 sq. ft.

The rudder is of the balanced type, with the balancing portion projecting forward under the body. It is recessed into the fin and body in the same manner as the flaps and tail. Maximum height, 3′-3″; depth rearward of the rudder post, 1′-11″; balanced portion, 7″ forward of the rudder post. Rudder area, 7.5 sq. ft.

Landing Gear

Great simplicity is seen in the landing chassis construction. It consists of a pair of 26″ by 3″ Ackerman spring wheels attached to a 1½″ diameter 3/16″ wall tube axle. Wheel tread, 5′-3″.

Chassis members are 1¼″ diameter 14 gage steel tube, streamlined with spruce fairing strips. Cross-wiring of heavy flexible cable.

The tail skid is mounted on a steel tube tripod, and sprung with rubber shock-absorber elastic cord.

Power Group

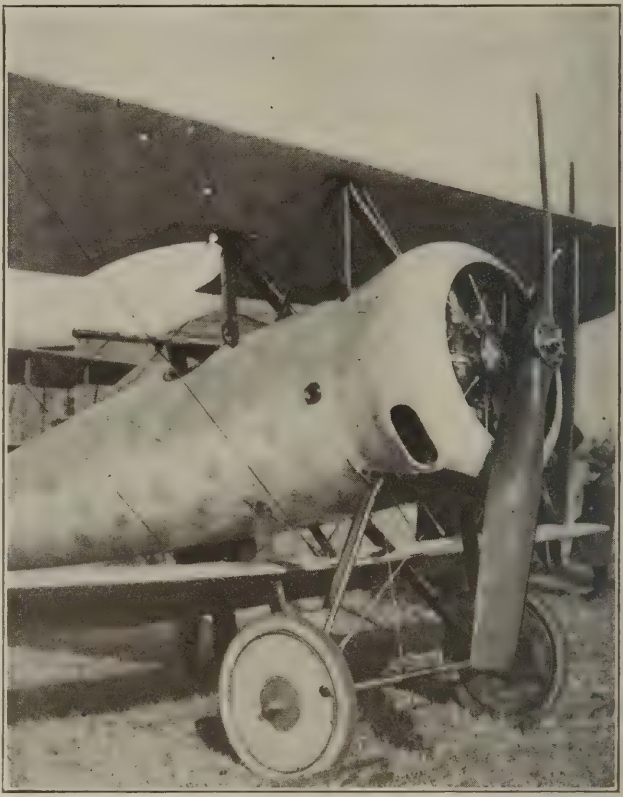
The engine is a rotary 9-cylinder General Vehicle Company's monosoupape Gnome. Bore, 110 mm; stroke, 150 mm. Rated H.P., 100 at 1,200 r.p.m. Weight, including vaporizer and ignition, 272 lbs. Fuel Consumption, 12 gallons per hour.

To assure a good supply of rich air to the vaporizer when the machine is banking or spiralling, and a vacuum liable to occur on one side of the body, two intake ducts are provided, one at either side of the body.

The propeller is 8′-4″ diameter with an 8′-9″ pitch.

The cowl surrounding the engine is of 1/16″ aluminum, reinforced with L section aluminum angle beam. An opening in the side of the cowl is made for the exhaust of the engine, and an opening at the bottom for cooling the cylinders and to facilitate removal.

Fuel is carried at either side of the fuselage interior in two 15-gallon tanks, running from the engine bulkhead to the rear of the cockpit and following the contour of the body. A 7-gallon oil tank is located at the top of the fuselage interior, just forward of the instrument board. The fuel is sufficient for a flight of 2½ hours.



Detail view of the Berckmans Scout, giving an idea of the chassis arrangement. (Passed by the Censor)

NEW AERONAUTIC BOOKS

Dictionary of Aviation

The "Dictionary of Aviation" compiled by Robert Morris Pierce, is published in a convenient, handy size, and while there have been many words written into the parlance of aeronautics since its appearance, it is a usable book, and decidedly worth its place on the desk of the aeronautical student. The attempt has been to produce a word book for the use of persons interested in aviation from any of the various points of view from which it may be contemplated. The price of the volume is $1.50.

Above the French Lines

Stuart Walcott, a young Princeton student who heard the call to arms prior to April, 1917, and who has since made the supreme sacrifice, wrote most interesting letters concerning his experiences, from the moment he started his flying tuition until shortly before the end, and these letters have been collected and issued by the Princeton Press in a small volume under the title "Above the French Lines." The letters tell in a chatty human way the life of the first band of bird men who went to France, and through it runs a vein of information which everyone going "over there" should have. Besides being instructive, the reader will find it immensely interesting.

En L' Air

War had been declared only two days between France and Germany, when Lieut. Bert Hall, then living in Paris, offered his services to France. He helped save Paris in the battle of the Marne, volunteered December 14, 1914, for aerial service, and became one of the ten original American members of the Lafayette Escadrille, of whom he and Major William Thaw are the only survivors. In August, 1916, he went to Russia and Roumania to assist these nations in connection with their air forces.

In his recently published book Lieut. Hall gives an intimate account of many experiences. Some of his descriptions of trench and air fighting are thrilling, and "En L'Air" has that atmosphere or reality that makes it a pleasure to peruse it. The price of the volume is $1.50.

Acquiring Wings

William B. Stout, pioneer aeronautic authority, now co-operating in a technical capacity with the Aircraft Board, has done the young aeronautic student a distinct service by publishing at this time his little volume "Acquiring Wings," which is couched in terms to answer the questionings of the prospective air student concerning the Why and the Wherefore of aviation. The work is written in easily understood terms, and the diagrams are particularly clear. After its perusal the reader has a very definite understanding of the theory of mechanical flight, and is well equipped to delve into more pretentious and technical works. The price of this volume is $.75.

Learning to Fly in the U. S. Army

E. N. Fales, assistant professor of mechanical engineering, chairman of aeronautics in the University of Illinois, has produced a manual of aviation practice under the title "Learning to Fly in the U. S. Army." The first chapter discusses briefly the history of aviation and subsequent chapters respectively, Types of Military Aeroplanes; Principles of Flight; Cross-country Flying; the Rigging of Aeroplanes—Nomenclature; Materials of Construction; Erecting Aeroplanes; Toning up the Fusilage; Handling of Aeroplanes. In other words, just exactly the volume of real practical value to the air student. The volume is well illustrated with half tones and line cuts. The price of the volume is $1.50.

The Way of the Air

The "spirit of the air" has often times been referred to in the daily points as something to be marvelled at, and the volume from the pen of Edgar C. Middleton, "The Way of the Air" gives many striking examples of this spirit. The author is a journalist, and consequently his pen pictures are particularly realistic; and his happy knack of making his reader experience his thrill with him makes the volume very enjoyable reading. In the latter section of the book he gives some excellent advice and suggestion to the young military airman. The price of the volume is $1.00.

THE CARWEN DYNAMIC BALANCING MACHINE

By G. DOUGLAS WARDROP

DURING the last twelve months the engineers of the Carlson-Wenstrom Company have devoted much time to the improvement of the Carwen dynamic balancing machine, which is founded on the Akimoff patents. The Akimoff patents were transferred to the Dynamic Balancing Machine Company, and the Carlson-Wenstrom Company are the exclusive licensees in the United States and important foreign countries.

The chief engineer of the Carlson-Wenstrom, **Mr. Jacob Lundgren,** is responsible for the recent improvements in the apparatus, which include a dial indicator which registers the amount of unbalance of the body; a flexible spring drive which increases the sensitiveness of the machine; a two-point balancing couple; operating the balancing couple while the machine is running; changing the relative angle of the balancing couple to an exact degree while the machine is in motion.

No matter how carefully an electric armature, automobile crankshaft, turbine rotor, centrifugal blower or separator, or the like be made, it rarely comes from the finisher's hands in perfect balance.

"Static" balance—such that the piece will remain in any position when placed on level ways—involves no great difficulty. But a body in perfect static balance may still develop a centrifugal couple leading to severe vibration at high rotative speeds.

So objectionable is this vibration with all the classes of apparatus named above, and many others, that much expense is incurred to machine non-working surfaces, and hours are spent in attempts to eliminate by trial and error the unbalanced couples, in order to minimize the ill effects of even a minute unbalance at high speeds.

Both the additional machine work and the larger part of the time thus spent are saved by the method here described.

The Carwen dynamic balancing machine determines in a few moments:

(1) The exact plane of unbalance.

(2) The exact amount of unbalance.

By applying the readings of the machine to a chart furnished with it one can determine at once exactly how much metal should be added or removed, and at what points, to produce a perfect running balance.

In repetition work, the machine will handle easily 100 automobile crankshafts or similar-sized parts in an 8-hour day; and there is absolutely no guesswork about its readings.

A man at a drill press, taking the shafts as they come tagged from the balancing machine, rapidly applies the corrections by drilling to the required depth at two points for a 4- or 8-cylinder shaft, two or sometimes three for a 6- or 12-cylinder, at a designated radius from the axis. Electric armatures, etc., are corrected almost as rapidly.

The whole process of setting in the Carwen machine, measuring the unbalance, and reading the chart, takes less than five minutes for an automobile crankshaft; and the result is better than has heretofore been obtainable with hours of careful trial.

Principle of Dynamic Balance

A body is in dynamic balance when there is no disturbing centrifugal couple acting on the axis of its rotation.

See figure 2, in which O is the common center of gravity, a the center of gravity of elements to the left, and b the center of gravity of elements to the right. The center of gravity of a and b is O; and O, being on the axis, will tend to remain stationary while the body is rotated. But a will develop a centrifugal force C measured by

$$C = \frac{W\,\Omega^2\,R}{g}$$

in which W is the weight concentrated at a, Ω is the angular velocity, R the radius of a, and g the acceleration due to gravity.

Similarly, b will develop a centrifugal force C',

$$C' = \frac{W'\,\Omega^2\,R'}{g}$$

But since the body is in static balance, $W\,R = W'\,R'$. Hence

$$C = C'$$

We therefore have two equal and opposite centrifugal forces, C and C', acting at a distance M to produce a rocking moment CM.

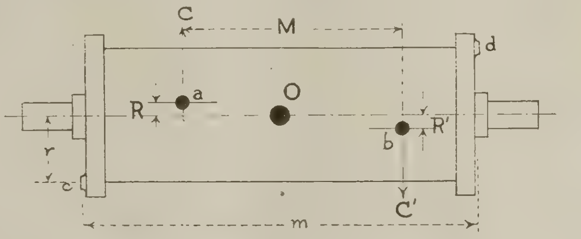


Figure 2. Body in static balance, but running unbalance. Corrective weights added at c and d.

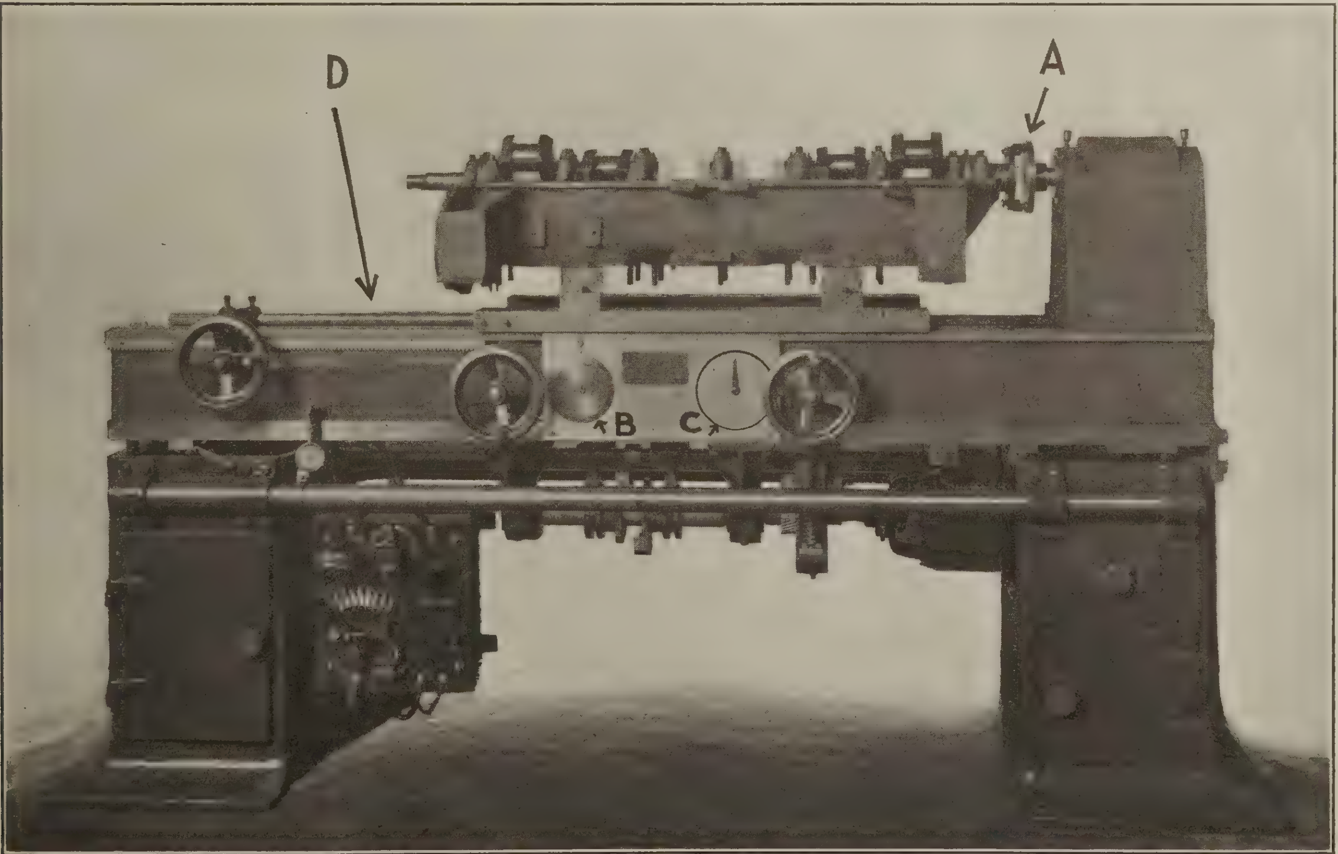

The Carwen Dynamic Balancing Machine. A shows the connection between the driving spindle and the body to be balanced, which has a degree of flexibility, because the slightest unalignment will cause enough shock to disturb the recording of the machine. B is the dial which registers the unbalance. C is the angle dial that indicates the relative position of the balancing couple. D indicates the bed on which brackets can be erected to balance a crankshaft out of its own bearing. The bearings in the bracket are removable and so arranged that when changing from one size to another no adjustment for height or alignment is required—the center of the bearing always being in line with the center of the spindle.

To neutralize this "centrifugal couple" it is necessary to add or remove metal at two points in the plane of unbalance, such that the centrifugal couple thereby produced shall balance the other.

Suppose metal to be added at c and d. It is not necessary that the distance m between c and d shall equal M. In fact, c and d may be quite arbitrarily located, so long as they are in the proper plane; it is only necessary that the "moment," or product of m by the centrifugal force due to c, shall be equal and opposite to the moment CM.

Let us put w = weight at c, and r = radius of c, which radius likewise may be arbitrarily chosen.

Then

$$C'' = \frac{w\,\Omega^2 r}{g}$$

where C'' is centrifugal force at c.

By assumption

$$CM = C''m \text{ or}$$

$$\frac{W\,\Omega^2 R M}{g} = \frac{w\,\Omega^2 r m}{g}$$

Cancelling $\qquad WRM = wrm$

That is, *the product of one compensating weight, its radius from the axis, and the distance between the weights, must equal the corresponding product for the hidden unbalance.* Also

$$\frac{w}{W} = \frac{RM}{rm} \text{ and } w = \frac{WRM}{rm}$$

Since r and m for the added weight w are arbitrary, it follows that if we can determine $W\ R\ M$ we can immediately fix the required value of w,—in other words, the amounts of metal to be added at the prescribed radius r and at points m inches apart.

To determine $W\ R\ M$ is the function of the Carwen dynamic balancing machine.

Principle of the Carwen Machine

In the Carwen machine the object to be balanced is supported and rotated on a bed which is fixed at one end, but free to vibrate at the other in one plane only under the influence of the unbalanced moment. Below and parallel to the body under test is another shaft, suspended from the bed and turning in the same direction at the same speed. See diagram, figure 3, in which A is the object tested, B the bed, and C the second shaft. On this latter shaft are known weights $D\ D$, which may be shifted while running to produce a centrifugal couple of variable but accurately measured amount. By varying the plane of these weights, and the distance between them, a position is found in which the unbalance due to the known weights exactly neutralizes the unbalance in the object tested. When this is done the vibration ceases.

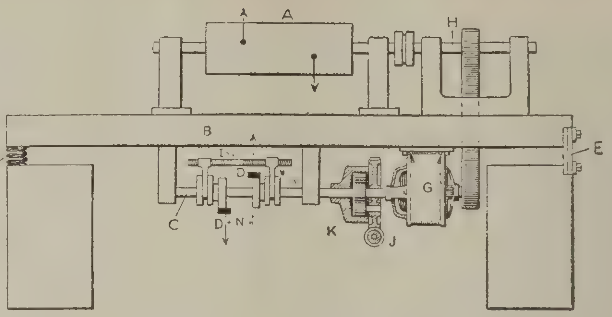

Figure 3. Principle of Carwen dynamic balancing machine. A, object under test; B, vibrating bed; C, spliced shaft carrying compensating weights D D; E, hinge; F, spring support; G, motor; H, head shaft; I, right and left hand screw; J, worm; K, internal gear of planetary drive. N, variable distance.

Under this condition the moment of the couple artificially produced by the known weights equals and neutralizes the hidden couple in the object tested; in other words, $W'\ R'\ M'$ for the compensating weights equals $W\ R\ M$.

But W' and R' for these weights are fixed, and M' (the only variable) can be directly measured. To simplify the matter still further, the product $W'\ R'\ M'$, of the weight, radius and distance apart of the weights, is arranged to be read in ounce-inches directly from the machine.

Ounce-inches, of course, vary with the speed of the machine, but so does the ounce-inches in the body to be balanced in the same proportion. The ounce-inches that the machine registers is the weight in ounces × radius and distance in inches, taken at a speed, for instance, where the centrifugal force is 1.

Since this product equals $W\ R\ M$, we have

$$w = \frac{W'R'M'}{rm}$$

in which the product $W'\ R'\ M'$ and both factors $r\ m$ are known.

If, instead of adding weights, we drill holes in specified locations, the task is further simplified by preparing charts showing the diameter and depths of holes. Thus the man at the drill press is required only to read a tag, made out for him by the balancing machine operator or assistant, from the readings of the chart.

Chart for finding weight of metal removed by drilling

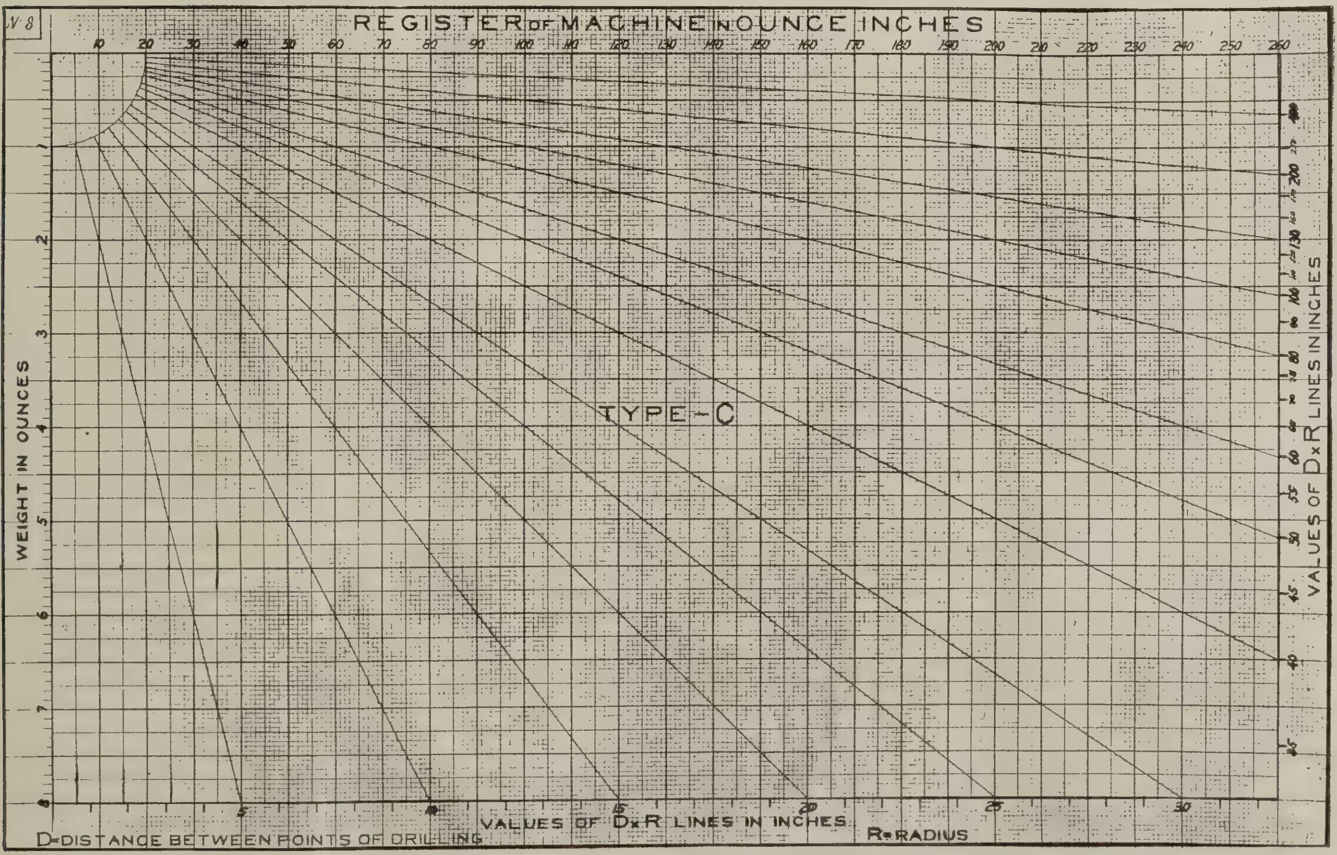

Chart for finding weight required in correcting unbalance

The compensating weights on the lower shaft are shifted to neutralize and thereby measure the unbalance in the object under test. By turning the two lower hand-wheels these weights are shifted without stopping the machine. Unbalance is read directly in ounce-inches from the semi-circular dial behind the left hand-wheels.

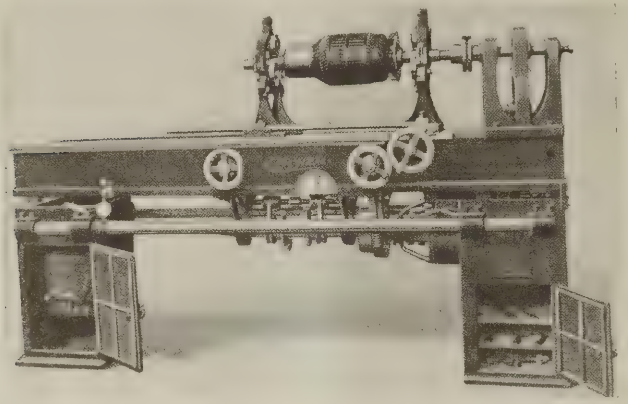

Figure 4. Carwen balancing machine, ready to test electric armature.

It might at first thought appear that the correct performance of the machine would require the centers of gravity of the object tested and of the counterbalancing weights to be located one above the other; but such is not the case. As a matter of fact, these centers of gravity may be anywhere within the capacity of the vibrating bed; and the fulcrum or hinge *E* on which the bed vibrates, instead of being located somewhere near the center, is located at the extreme right-hand end. All that is necessary is that the *moments* of the unbalanced object and the compensating weights shall be equal and opposite. These moments, acting about a common fulcrum (the hinge), produce the same effect, regardless of the exact location of the object or the compensating weights.

Construction of the Machine

The bed, which somewhat resembles a lathe bed, is supported on two box pedestals. At the right end is the "hinge"—two heavy plates of spring steel, bolted to the bed and to the pedestal. At the other end the bed rests merely one one or more short helical springs *F*, and is confined to vertical motion by a steadying strip of steel. See figure 5. The bed has no other connection with the pedestals.

Suspended from the bed is an electric motor, which drives the head shaft *H* through a train of gears. This shaft drives the object under test through a flexible coupling.

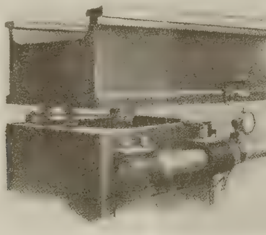

Figure 5. Left end of bed, showing spring supports, vibration indicator, and steadying strip which prevents lateral vibration. For heavier weights more springs are used. The finger lever at left of indicator is raised to touch the bed and thereby check vibrations.

Suspended in line with the motor is a shaft *C*, on which are splined the two compensating weights *D D*, connected to flanged collars through which a pair of forks moves them away from or toward each other. The left hand-wheel, through a pair of mitre gears, rotates the right and left hand screw *I* which moves the forks. The right-hand fork carries a rack from which a pinion actuates the index finger on the semi-circular dial, showing the distance between the weights. Fractional readings are taken from the dial behind the left hand-wheel. Readings are in ounce-inches, signifying the product of the weight in ounces of one counterweight, the radius of its center of gravity from the shaft axis, and the horizontal distance between the counter weight centers.

To permit the angular position of the compensating weights to be varied without stopping the machine, the shaft *C* carrying the weights is not coupled directly to the motor shaft, but is driven through a planetary gear. A spur pinion on the motor shaft meshes with a pinion carried by a cage, and this pinion engages an internal gear *K* on shaft *C*. The cage has a worm gear cut on the periphery, and by turning the lower right hand-wheel the cage is rotated, thereby changing the angular position of the counterweight shaft.

A dial angle indicator on the right side is connected with this wheel, showing the relative angle of the couple to the body being balanced.

The arrangement in figure 3 is merely diagrammatic, but shows the principle.

The gearing is such that both the test object and the counterweight shaft rotate in the same direction and at the same speed. A high speed is not necessary, as the machine is extremely sensitive. About 450 r. p. m. is usually enough, though the motor will give lower and higher speeds.

The amount of vibration is indicated by the micrometer indicator attached between the left end of the bed and the front bar joining the pedestals. To stop the vibrations quickly, the small finger lever is raised till it touches the bed.

The upper right hand-wheel is removable, and may be attached to either of the work supports for the purpose of shifting them on the bed.

Procedure When Testing

The first step in testing, after setting the piece to be tested, is to offset the compensating weights by some small distance and then use the lower right hand-wheel to vary the plane of the weights till the position of the least vibration is found.

Using the left hand-wheel, the weights are now shifted in and out, and the micrometer indicator watched. When the minimum vibration —now very small—is found, the other hand-wheel is again used for a final correction on the angular plane. The machine will now run perfectly smooth.

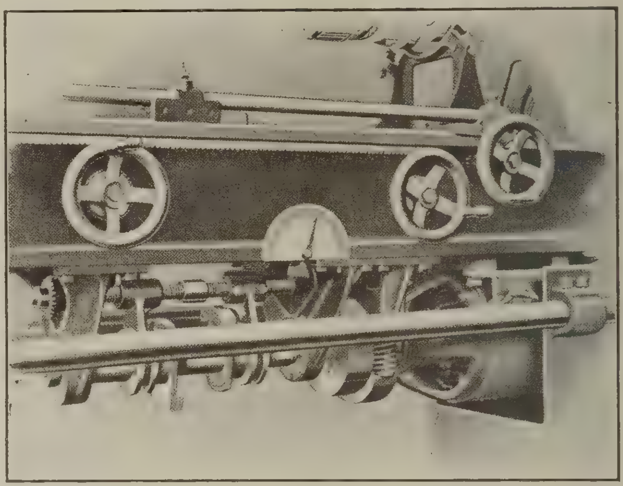

Figure 6. Details of Carwen Dynamic Balancing Machine.

Stopping with the counterweights vertical (indicated by marks on *K*), the plane of unbalance is marked on the object, and the readings are taken from the semi-circular and left hand-wheel dials and entered on a tag.

General Notes on Balancing

Throughout the foregoing it has been assumed that the piece to be balanced has already been put in static balance. This is essential, as static and dynamic balancing are entirely different processes. We furnish a simple machine by which the static unbalance can readily be measured.

Since the piece is already in static balance, which balance must not be altered, it follows that the weights added or deducted on each of the axis are equal if their radii are equal. In other words, the holes will be of equal diameter and depth.

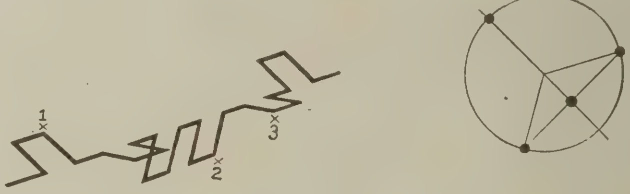

Figure 7. Principle of balancing 6-throw shaft where unbalance lies in plane of crank 1.

A special case is presented by six-cylinder crankshafts, which require correction in three planes instead of one, if the plane of unbalance lies in the line of one of the crank planes. The solution, however, is very simple. While one of the cranks in this plane may be drilled, the other cannot, since it is on the same side of the axis. It is therefore necessary to drill two other cranks, one in each of the other planes. For this purpose two adjacent cranks are chosen, and each is drilled to the same size, depth and radius as the first crank. See figure 7. The reason is that the center of gravity of these two latter holes is midway between them, at a distance from the shaft axis exactly one-half the radius of the holes (cosine 60° = .5). Thus the two holes have the same effect as one at the full radius; and, moreover, they are so spaced as not to upset the static balance in relation to hole No. 1. The moment, of course, is figured from No. 1 hole to a plane midway between the transverse planes of holes Nos. 2 and 3.

In some cases where the plane of unbalance falls between any of the crank cheeks and the corrections must be made somewhere outside the line of the plane of unbalance, the following chart will help determine (Blueprint No. 3) the amount of metal to be removed, and where, which in this case would be in four different points, two of those points falling in the same crank, weight necessary for correction would be calculated the same as if the unbalance fell in the center of one of the cranks. This valve obtained then to be multiplied with *A* and *B* for the angle *V* between the center of the crank and the plane of unbalance. The other two points at *A* and *W* would be obtained in the same way for an angle equal to 60° minue *V*. The distance between the point of correction in this case would be the mean distance between *A* and *B* to the mean distance between *A* and *W*. The radius where the corrections are made would remain the same as the radius used in the first calculation.

To facilitate rapid handling of duplicate objects two roller bearing supports are provided, as shown. To change the piece tested it is only necessary to release the top roller. A special drive is furnished for connecting to flanged crank shafts, which ensures flexibility to allow for slight variations in alignment but prevents back lash.

TO USE TABLE:- MULTIPLY "A" & "B" BY VALUE OF "W" GIVEN BY MACHINE

CHART FOR SIX CYLINDER CRANK SHAFT

Operation

The body to be balanced should first of all be put in static balance; that is, when the same is put on level ways, it should be at rest in any position. To obtain perfect running or dynamic balance, it is very important to have correct static balance. If the machine fails to register the dynamic unbalance properly, it is due to poor static balance. After correcting for static balance, put body in the balancing machine and regulate speed until vibrations become uniform—if there are no vibrations, the body is in balance—offset the balancing weights a small distance with the left hand-wheel and turn the right hand-wheel until the minimum vibrations are recorded which shows that the angular plane of unbalance is found, then shift the weights in either direction with the left hand-wheel until the micrometer dial becomes stationary, when the unbalance indicator will show the amount in measures marked on the face of the dial (for *C* machine, ounce-inches or ctm. kg.)—on the disc at the right end of the balancing cage are two lines opposite each other, one plain, and one marked *O* when stopping the machine on the *O* line metal is to be *removed* on top towards right, and bottom towards left in correcting unbalance. When stopping machine on plain line, metal is to be *added* for correspecting in same places.

The weight required to correct the unbalance is obtained as follows:

if S = Register of unbalance in ounce inches
D = Distance in inches between points where correction is made
R = Radius in inches, point of correction to center of body
W = Weight required in ounces,

$$\text{then } W = \frac{S}{D \times R}$$

As $D \times R$ in most cases can be made a constant for each type of bodies to be balanced, this factor is represented by straight lines converging to the center in the upper left-hand corners of 'the charts furnished, the top figures indicate the register of the machine, and the figures on the left indicate the necessary weight where the two intersect the line representing the value of $D \times R$.

As an illustration on "C" chart.

$$\left.\begin{array}{l}\text{The radius R} = 3\\ \text{Distance} \quad\;\; = 5\end{array}\right\} D \times R = 15''$$

Register of machine—60 ounce inches.

Follow 60 from top of chart until the 15" line is reached. The figure on the left opposite intersection is 4, the weight required to correct the unbalance.

Standard sizes of Carwen Dynamic Balancing Machines are built to handle objects of the following dimensions:

Type	Approx. Weight in Lbs. Handled	Capacity of Unbalance	L'ngth of Bed	Width of Bed	Largest Length Handled	Swing	Floor Space
AAA	¼ to ¾	½ oz.-inches	7"	2"	4"	2"	15"x18"
AA	¾ to 3 lbs.	4 oz.-inches	10"	3"	7"	3½"	15"x15"
A	3 to 10 lbs.	18 oz.-inches	18"	4"	14"	5"	20"x20"
B	10 to 30 lbs.	64 oz.-inches	30"	8"	24"	8"	36"x14"
C	30 to 125 lbs.	288 oz.-inches	6' 10"	14"	5'	20"	7' 6"x22"
D	125 to 500 lbs.	360 oz.-inches	7' 2"	14"	5' 6"	22"	7' 10"x22"

Section drawings of one of the Carwen Dynamic Balancing Machines—Type C

INTERNATIONAL AIRCRAFT STANDARDS

Adopted by the International Aircraft Board

The International Aircraft Standards Board, of the Advisory Commission of the Council of National Defense has formulated the following specifications in addition to those concluded on page 161.

Specifications for Mercerized Cotton Aeroplane Fabric (Grade A)
(2F1 April, 1918)

General.—1. The general specifications 1G1 shall form, according to their applicability, a part of these specifications.

Material.—2. (*a*) The warp and filling yarns used in the manufacture of this fabric must be size 2/60, according to the English cotton yarn numbers. A tolerance of plus or minus four (±4) will be allowed in the size of single yarns.

(*b*) The length of the staple of the fabric must not be less than 1½ inches.

Manufacture.—3. (*a*) The yarn shall be combed (single or double) and shall be mercerized under tension.

(*b*) It is recommended that the single yarn be given 28 to 34 turns per inch of twist and that 16 turns per inch be used for twisting these yarns together. This procedure may be altered provided that the fabric conforms to this specification in other respects.

(*c*) There must be at least 80 threads and not more than 84 threads per inch in both warp and filling.

(*d*) The weave shall be plain weave.

(*e*) The fabric must be uniform in structure and free from manufacturing imperfections.

(*f*) The fabric, under normal moisture conditions, must not weigh more than 4.5 ounces per square yard.

(*g*) The width must be 36 inches.

Physical Properties and Tests.—4.—*Tensile Test.*—(*a*) The tensile test specimens, prepared in accordance with paragraphs 5(*a*), 5(*b*), and 5(*c*), shall be exposed for at least two hours in an atmosphere of 65 per cent relative humidity at 70° F. (21° C.) and then tested in this atmosphere.

(*b*) The distance between the jaws or clamps of the testing machine at the beginning of the test shall be 8 inches (20 cm.). The pulling jaw shall move at the rate of 12 inches per minute during the test.

(*c*) The average breaking load of the five specimens cut in the direction of the warp and the average breaking load of the five specimens cut in the direction of the filling, as shown in Fig. 1, must each be at least 80 pounds.

(*d*) The elongation shall be observed when the specimens are subjected to each of the loads given in Table 1.

(*e*) Whenever practicable, an autographic record shall be taken.

(*f*) The elongation must not exceed the values given in Table 1 by more than 10 per cent.

(*g*) The average results for both warp and filling shall be reported separately.

Table 1.

Tension in pounds.	Elongation in inches, warp.	Elongation in inches, filling.
10	0.65	0.32
20	.80	.40
70	1.20	.64

Test for Sizing.—(*h*) Tests for sizing shall be conducted as follows:

(1) Dry samples weighing approximately 0.18 ounce (5 gm.) in tared weighing bottles at 221 to 230° F. (105 to 110° C.) to constant weight.

(2) Boil the samples in water for 10 minutes and rinse thoroughly.

(3) Digest each sample in a solution containing 15 centimeters commercial diastofor in 500 centimeters water at 140° F. (60° C.) for two hours.

(4) Wash thoroughly in hot water and then boil for one hour in 500 centimeters distilled water and wash again.

(5) Dry in tared weighing bottles to constant weight.

(6) Percentage sizing $= \dfrac{\text{loss in weight}}{\text{original weight}} \times 100.$

(*i*) The fabric must not contain more than 3.5 per cent of sizing, as determined by the above method.

Mercerization Test.—(*j*) Take approximately one-fourth square foot of the cloth, immerse in boiling distilled water and stir occasionally while cooling. At the end of of 10 minutes place a strip of blue and a strip of red litmus paper into the liquid with the fabric and allow them to remain 5 minutes. At the end of this time the litmus papers must have retained their original colors. Any cloth showing either an acid or alkaline reaction shall be rejected. This test may be made on the yarn before weaving by substituting a small handful of the yarn for the cloth sample.

Selection of Test Specimens.—5. (*a*) Samples for tests shall be taken from at least five bolts in each warp woven.

(*b*) The sample taken from a bolt shall be 1 yard long and the full width of the bolt; it shall be cut from the fabric at a point 10 yards from the end of the bolt.

(*c*) Test specimens for tensile tests, 12 inches long and 1¼ inches wide, shall be cut from each sample taken as shown in Fig. 1. Threads shall be pulled out from the sides of the test specimens until a width of 1 inch of woven fabric remains.

Inspection and Rejection.—6. The inspector shall mark all accepted material close to the end of each bolt with the official acceptance stamp. Rejected material shall be marked with the rejection stamp and shall not be resubmitted without the express consent of the purchaser. The acceptance and rejection stamps shall be so placed that they do not injure the material, or, in the case of rejected fabric, so that the marking does not preclude the use of the material for other than aircraft work.

Replacements.—7. All fabric that does not conform to this specification shall be rejected and shall be replaced by the manufacturer at his expense.

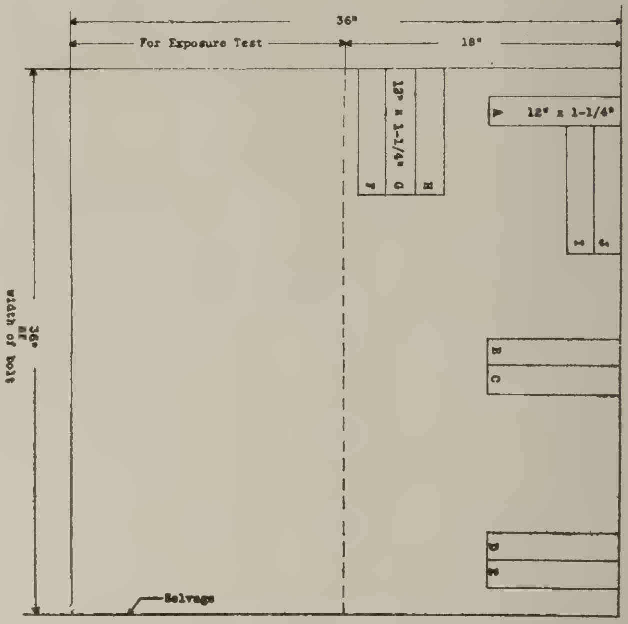

Fig. 1.—*Sketch showing the location of the 10 test specimens (lettered A to F) to be cut from the sample.*

Specifications for Unmercerized Cotton Aeroplane Fabric (Grade A)
(2F2 April, 1918)

General.—1. The general specifications 1G1 shall form, according to their applicability, a part of these specifications.

Material.—2. (*a*) The warp and filling yarns used in the manufacture of this fabric must be size 2/60, according to the English cotton-yarn numbers. A tolerance of plus or minus four (±4) will be allowed in the size of single yarns.

(*b*) The length of the staple of the fabric must not be less than 1½ inches.

Manufacture.—3. (*a*) The yarn shall be combed (single or double).

(*b*) It is recommended that single yarn be given 22 to 25 turns per inch of twist and that 25 to 26 turns per inch be used for twisting this yarn together. This procedure may be altered provided that the fabric conforms to this specification in other respects.

(*c*) There must be at least 93 threads per inch in warp and 86 threads per inch in filling. A tolerance of plus or minus two (±2) threads will be allowed.

(*d*) The weave shall be a plain weave.

(*e*) The fabric must be uniform in structure and free from manufacturing imperfections.

(*f*) The fabric, under normal moisture conditions, must not weigh more than 4.5 ounces per square yard.

(*g*) The width must be 36 inches.

Physical Properties and Tests.—4.—*Tensile Test.*—(*a*) The tensile test specimens, prepared in accordance with paragraphs 5 (*a*), 5 (*b*), and 5(*c*), shall be exposed for at least two hours in an atmosphere of 65 per cent relative humidity at 70° F. (21° C.) and then tested in this atmosphere.

(*b*) The distance between the jaws or clamps of the testing machine at the beginning of the test shall be 8 inches (20 cm.). The pulling jaw shall move at the rate of 12 inches (30 cm.) per minute during the test.

(*c*) The average breaking load of five specimens cut in the direction of the warp and the average breaking load of the five specimens cut in the direction of the filling, as shown in Fig. 1, must each be at least 75 pounds.

(*d*) The elongation shall be observed when the specimens are subjected to each of the loads given in Table 1.

(*e*) Whenever practicable an autographic record shall be taken.

(*f*) The elongation must not exceed the values given in Table 1 by more than 10 per cent.

(*g*) The average results for both warp and filling shall be reported separately.

Table 1.

Tension in pounds.	Elongation in inches, warp.	Elongation in inches, filling.
10	0.74	0.42
20	.94	.53
70	1.44	.90

Test for Sizing.—(*h*) Tests for sizing shall be conducted as follows:

(1) Dry samples weighing approximately 0.18 ounce (5 gm.) in tared weighing bottles at 221 to 230° F. (105 to 110° C.) to constant weight.

(2) Boil the samples in water for 10 minutes and rinse thoroughly.

(3) Digest each sample in a solution containing 15 cubic centi-

meters commercial diastofor in 500 cubic centimeters water at 140° F. (60° C.) for two hours.

(4) Wash thoroughly in hot water and then boil for one hour in 500 cubic centimeters distilled water and wash again.

(5) Dry in tared weighing bottles to constant weight.

(6) Percentage sizing $= \frac{\text{loss in weight}}{\text{original weight}} \times 100.$

(*i*) The fabric must not contain more than 3.5 per cent of sizing, as determined by the above method.

Selection of Test Specimens.—5. (*a*) Samples for tests shall be taken from at least five bolts in each warp woven.

(*b*) The sample taken from a bolt shall be 1 yard long and the full width of the bolt; it shall be cut from the fabric at a point 10 yards from the end of the bolt.

(*c*) Test specimens for tensile tests, 12 inches long and 1¼ inches wide, shall be cut from each sample taken as shown in Fig. 1. Threads shall be pulled out from the sides of the test specimens until a width of 1 inch of woven fabric remains.

Inspection and Rejection.—6. The inspector shall mark all accepted material close to the end of each bolt with the official acceptance stamp. Rejected material shall be marked with the rejection stamp and shall not be resubmitted without the express consent of the purchaser. The acceptance and rejection stamps shall be so placed that they do not injure the material, or, in the case of rejected fabric, so that the marking does not preclude the use of the material for other than aircraft work.

Replacements.—7. All fabric that does not conform to this specification shall be rejected and shall be replaced by the manufacturer at his expense.

Specifications for Mercerized Cotton Aeroplane Fabric (Grade B)
(2F3 April, 1918)

General.—1. (*a*) The general specifications 1G1 shall form, according to their applicability, a part of these specifications.

Material.—2. The warp and filling yarns used in the manufacture of this fabric must be size 3/80, according to the English cotton yarn numbers. A tolerance of plus or minus four (±4) will be allowed in the size of single yarns.

(*b*) The length of the staple of the fabric must not be less than 1½ inches.

Manufacture.—3. (*a*) The yarn shall be combed (single or double) and shall be mercerized under tension.

(*b*) It is recommended that the single yarn be given 36 to 40 turns per inch of twist and that 18 to 20 turns per inch be used for twisting these yarns together. This procedure may be altered, provided that the fabric conforms to this specification in other respects.

(*c*) There must be at least 68 threads and not more than 72 threads per inch in both warp and filling.

(*d*) The weave shall be a plain weave.

(*e*) The fabric must be uniform in structure and free from manufacturing imperfections.

(*f*) The fabric, under normal moisture conditions, must not weigh more than 4 ounces per square yard.

(*g*) The width must be 36 inches.

Physical Properties and Tests.—4.—*Tensile Test.*—(*a*) The tensile test specimens, prepared in accordance with paragraphs 5 (*a*), 5 (*b*), and 5(*c*), shall be exposed for at least two hours in an atmosphere of 65 per cent relative humidity at 70° F. (21° C.) and then tested in this atmosphere.

(*b*) The distance between the jaws or clamps of the testing machine at the beginning of the test shall be 8 inches (20 cm.). The pulling jaw shall move at the rate of 12 inches per minute during the test.

(*c*) The average breaking load of the five specimens, cut in the direction of the warp and the average breaking load of the five specimens cut in the direction of the filling, as shown in Fig. 1, must each be at least 73 pounds.

(*d*) The elongation shall be observed when the specimens are subjected to each of the loads given in Table 1.

(*e*) Whenever practicable an autographic record shall be taken.

(*f*) The elongation must not exceed the values given in Table 1 by more than 10 per cent.

(*g*) The average results for both warp and filling shall be reported separately.

Table 1.

Tension in pounds.	Elongation in inches, warp.	Elongation in inches, filling.
10	0.70	0.44
20	.86	.52
65	1.19	.78

Test for Sizing.—(*h*) Tests for sizing shall be conducted as follows:

(1) Dry samples weighing approximately 0.18 ounce (5 gm.) in tared weighing bottles at 221 to 230° F. (105 to 110° C.) to constant weight.

(2) Boil the samples in water for 10 minutes and rinse thoroughly.

(3) Digest each sample in a solution containing 15 cubic centimeters commercial diastofor in 500 cubic centimeters water at 140° F. (60° C.) for two hours.

(4) Wash thoroughly in hot water and then boil for one hour in 500 cubic centimeters distilled water and wash again.

(5) Dry in tared weighing bottles to constant weight.

(6) Percentage sizing $= \frac{\text{loss in weight}}{\text{original weight}} \times 100.$

(*i*) The fabric must not contain more than 3.5 per cent of sizing, as determined by the above method.

Mercerization Test.—(*j*) Take approximately one-fourth square foot of the cloth, immerse in boiling distilled water, and stir occasionally while cooling. At the end of 10 minutes place a strip of blue and a strip of red litmus paper into the liquid with the fabric and allow them to remain 5 minutes. At the end of this time the litmus papers must have retained their original colors. Any cloth showing either an acid or alkaline reaction shall be rejected. This test may be made on the yarn before weaving by substituting a small handful of the yarn for the cloth sample.

Selection of Test Specimens.—5. (*a*) Samples for tests shall be taken from at least five bolts in each warp woven.

(*b*) The sample taken from a bolt shall be 1 yard long and the full width of the bolt; it shall be cut from the fabric at a point 10 yards from the end of the bolt.

(*c*) Test specimens for tensile tests, 12 inches long and 1¼ inches wide, shall be cut from each sample taken, as shown in Fig. 1. Threads shall be pulled out from the sides of the test specimens until a width of 1 inch of woven fabric remains.

Inspection and Rejection.—6. The inspector shall mark all accepted material close to the end of each bolt, with the official acceptance stamp. Rejected material shall be marked with the rejection stamp and shall not be resubmitted without the specific consent of the purchaser. The acceptance and rejection stamps shall be placed so that they do not injure the material, or, in the case of rejected fabric, so that the marking does not preclude the use of the material for other than air craft work.

Replacement.—7. All fabric that does not conform to this specification shall be rejected and shall be replaced by the manufacturer at his expense.

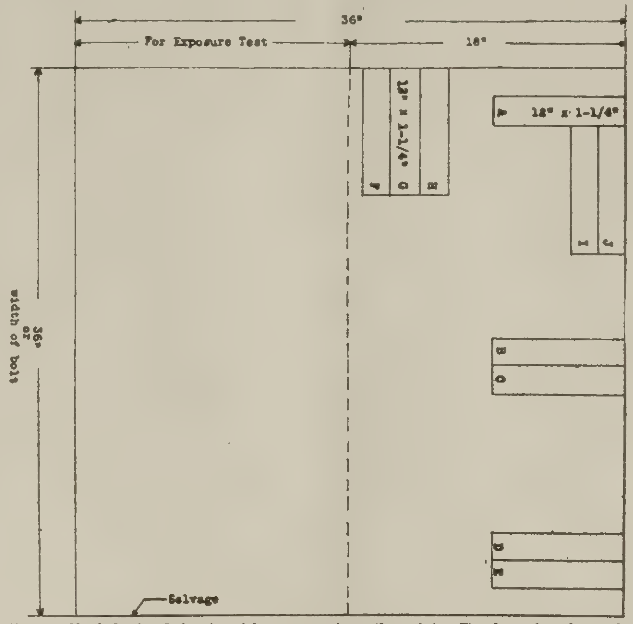

Fig. 1.—*Sketch showing the location of the 10 test specimens (lettered A to F) to be cut from the sample.*

Specifications for Unmercerized Cotton Aeroplane Fabric (Grade B)
(2F4 April, 1918)

General.—1. The general specification 1G1 shall form, according to their applicability, a part of these specfications.

Material.—2. (*a*) The warp and filling yarns used in the manufacture of this fabric must be size 3/80, according to the English cotton yarn numbers. A tolerance of plus or minus four (±4) will be allowed in the size of single yarns.

(*b*) The length of the staple of the fabric must not be less than 1½ inches.

Manufacture.—3. (*a*) The yarn shall be combed (single or double).

(*b*) It is recommended that the single yarn be given 36 to 40 turns per inch of twist and that 18 to 20 turns per inch be used for twisting these yarns together. This procedure may be altered provided that the fabric conforms to this specification in other respects.

(*c*) There must be at least 68 threads and not more than 72 threads per inch in both warp and filling.

(*d*) The weave shall be a plain weave.

(*e*) The fabric must be uniform in structure and free from manufacturing imperfections.

(*f*) The fabric, under normal moisture conditions, must not weigh more than 4.2 ounces per square yard.

(*g*) The width must be 36 inches.

Physical Properties and Tests.—4.—*Tensile Test.*—(*a*) The tensile test specimens, prepared in accordance with paragraphs 5 (*a*), 5 (*b*), and 5 (*c*), shall be exposed for at least two hours in an atmosphere of 65 per cent relative humidity at 70° F. (21° C.) and then tested in this atmosphere.

(*b*) The distance between the jaws or clamps of the testing machine, at the beginning of the test, shall be 8 inches (20 cm.). The pulling jaw shall move at the rate of 12 inches per minute during the test.

(*c*) The average breaking load of the five specimens, cut in the direction of the warp and the average breaking load of the five specimens cut in the direction of the filling, as shown in Fig. 1, must each be at least 70 pounds.

(*d*) The elongation shall be observed when the specimens are subjected to each of the loads given in Table 1.

(*e*) Whenever practicable an autographic record shall be taken.

(*f*) The elongation must not exceed the values given in Table 1 by more than 10 per cent.

(*g*) The average results for both warp and filling shall be reported separately.

Table 1.

Tension in pounds.	Elongation in inches, warp.	Elongation in inches, filling.

MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MMP—Report to Middletown Aviation Supply Warehouse, Middletown, Pa.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PRC—Appointment to Aviation Section declined; prefers retaining previous commission.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
PWM—Report to Payne Field, West Point, Miss.
REL—Relieved from present duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRV—Report to Aviation Depot, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SAG—Report to Souther Field, Americus, Ga.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
TFT—Report to Taliaferro Field, Fort Worth, Texas. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UCB—Report to School of Military Aeronautics, University of California, Berkeley, Cal.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WAC—Report to Aviation Concentration Camp, Waco, Tex.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WFO—Report to Wilbur Wright Field, Fairfield, Ohio.

Note 1.—Report to points named for temporary duty in the order given.

Note 2.—Report to district manager of equipment, Detroit, Mich.

Note 3.—Report to district manager of equipment, 15 Park Row, New York City.

Note 4.—Report to Signal Corps Recruit Bureau, Fort Wayne, Mich.

Note 5.—Report to Production Engineering Division, Curtiss factory, Buffalo, N. Y.

Note 6.—Report to Ballon Detachment, Fort Monroe, Va.

Note 7.—Report to Captain Paul B. Holmes, 870 Woodward Ave., Detroit, Mich.

Note 8.—Report to oil branch, fuel and forage division, Quartermaster's Corps, 51 Chambers Street, New York City.

Note 9.—Report to commanding general, Eastern Department, for duty with Departmental Aeronautic Officer, New York City.

Note 10.—Report to District Approvals Officers, Lindsey Building, Washington, D. C.

Note 11.—Report to San Antonio, Texas, at Aviation Construction Camp.

Note 12.—Report to Camp Alfred Vail, Little Silver, N. J.

Note 13.—Proceed to New York, N. Y., for permanent station.

FOREIGN NEWS

CANADA

The Department of Indian Affairs of the Dominion Government has decided to allow the Indians to sell spruce timber for aeroplane purposes on the Tscheacton reserve. O. Bowman of Chilliwack has completed a shipment of two cars of spruce for this purpose.

FRANCE

The French official announcement of April 15th says:

"During April 13th and 14th four enemy aeroplanes were shot down. Our bombing machines dropped 3,000 kilograms of projectiles upon enemy establishments and convoys in the region of Montdidier."

The following aeronautical operations are reported on April 17th:

"On April 15th and 16th four German aeroplanes were brought down. It is confirmed that two additional enemy machines were destroyed April 12th."

Extensive aerial operations are summarized in the French official announcement of April 20th:

"On the night of April 18th-19th nearly four tons of projectiles were dropped by fifteen of our aeroplanes on the landing ground at Champion and bivouacs in the region of Ham, Guiscard, and Noyon.

"On April 19th thirteen of our aeroplanes, in two expeditions, dropped 1,860 kilograms of explosives on the enemy organization in the region of Roye and Moreuil.

"On the night of 19th-20th seventy aeroplanes very effectively bombed the railway station at St. Quentin and numerous railways in the region of Jussy, as well as aviation grounds. More than fifteen tons of explosives were dropped.

"Another group of seven machines bombed the railway stations at Mont Cornet, Asfeld, and Hirson, and the aviation ground at Clermont-les-Fermes. Air patrols, flying at a low altitude, machine-gunned resting troops.

"It is confirmed that three additional aeroplanes have been brought down."

An enemy aeroplane succeeded in passing observation posts without being reported and flew over the district, says an official note, issued at Havre.

Several bombs were dropped near one of the camps for German prisoners. The material damage was slight and there were no casualties.

GERMANY

Enormous loss was caused by the fire which destroyed the Zeppelin works at Manzel, near Friedrichshafen. The plant had been transformed for the manufacture of aeroplanes of the Gotha type, according to reliable reports from Rorschach, on Lake Constance. Vast quantities of raw materials were burned, and it is reported at Constance that two large Zeppelins and forty aeroplanes also were destroyed, comprising the whole fleet then at the plant.

Many warehouses were reduced to ashes, as also were the offices of the plant, situated close to the workshops.

The fire broke out between 10 and 11 o'clock on Saturday and burned all day Sunday, according to two Swiss travellers who were in Friedrichshafen Sunday. The fire began with an explosion, and there were frequent explosions throughout Saturday night and the following day, apparently due to the bursting of gasoline tanks and hydrogen cylinders.

There was something like a panic in the town, where several houses were set on fire and others damaged. Masses of debris were hurled into the air by the explosions.

The material losses in the fire which destroyed the aircraft factories near Friedrichshaften were enormous, including thirty squadrons of aeroplanes reserved for use against the American air fleet, it was announced.

One hundred and forty persons were killed and 200 injured.

British and French air raids on Bavarian cities are increasing steadily and the damage to property, especially in the Palatinate, is very extensive.

This fact was brought to the attention of the Bavarian Chamber of Deputies by a Socialist interpellation asking:

"Is the Government aware of the fact that the population of Bavaria, and especially of the Palatinate, is suffering great material losses as a result of the steadily increasing aerial attacks? What does the Government intend to do regarding the compensation of those affected?"

The Socialists stated that hostile aerial attacks on a number of cities recently had increased greatly. Minister of the Interior von Brettreich said that the Palatinate had suffered severely from the recent aerial attacks, but for obvious reasons he could not dwell on the extent and the character of the damage. The Bavarian Government, he said, was willing to grant compensations for damage to property caused by hostile fliers.

GREAT BRITAIN

British aeroplanes did much low flying on April 15th and 16th, according to a New York *Herald* dispatch, above La Bassée-Estaires road, demoralizing the enemy's transport and artillery coming up to stiffen the Merville front. There has been a steady movement forward of additional heavy batteries, but the British airmen have delayed them greatly with bombs and machine gun attacks.

An official report on aerial operations April 16th says:

"Bad weather prevailed Monday, and there was only low flying. Four tons of bombs were dropped on different targets. No German aircraft were encountered. One of our machines is missing."

The British official communication dealing with aviation, issued April 19th says:

"The weather made it impossible Thursday for our aeroplanes to carry out more than low reconnoissances and to drop a few bombs on the area. At night nine tons of bombs were dropped on Bapaume, Armentieres and Warneton, and the railway junction at Chaulnes.

"All of our machines returned."

The British official communication dealing with aviation on April 21st says:

"The weather improved Saturday, but thick clouds prevented flying at high altitudes. Twelve tons of bombs were dropped on various targets, including Armentieres and the Thourot railroad junction.

"During the last few days, owing to better weather, there has been more air fighting. Six hostile machines were downed and three others disabled. Three of our machines are missing.

"Our night flying squadrons bombed Bapaume and enemy billets and the roads leading to the front. Hostile railway junctions also were attacked at Chaulnes, where a large fire was caused; at Junivelle, twenty miles northeast of Rheims, and at Bethenville. All our machines returned."

Stories of the magnificent work done by the British airmen continue to be recorded. None is more striking than a battle in which a British machine with a pilot and observer was attacked by eight enemy aeroplanes, reported by the Associated Press.

Terrific fighting ensued. The British aeroplane engaged the enemy so fiercely that three hostile machines were driven down out of control in the first few minutes of the engagement. The Germans were pumping streams of bullets into the British machine, and the observer was carrying on the fight after having been wounded in six places.

The British machine finally was so badly damaged that it caught fire and dived steeply. The pilot and wounded observer continued to engage the remaining five German machines, while their own was descending in flames.

The British aeroplane eventually crashed in No Man's Land, over which the German infantry were firing steadily with machine guns. The British infantry, however, organized a rescue party and brought the airmen back safely.

It is officially announced that the Committee on Production has approved an arrangement under which plain time workers in federated establishments wholly engaged in the manufacture of aircraft or aircraft parts have received a bonus of 12½ per cent on earnings.

Rear-Admiral Mark Kerr, a member of the Air Council, said recently that one of the first air routes the French are going to establish after the war is to Timbuctoo, when the journey will then only take four days, whereas it used to occupy four months. As a commercial undertaking that will result in a great saving. Four months' food alone would be a considerable item.

During one of the recent air raids, the largest anti-aircraft gun in the London district was worked by a gunlayer armed cap-a-pie in medieval plate armor, a breech-worker clad in chain mail, and a sight-setter attired in silk tights and a velvet coat.

The reason for this motley attire was that the alarm came while the gun crew were taking part in some amateur theatricals in their barracks, and they rushed off the stage in their medieval attire straight to their duties on the gun platform.

Every honor for valor that a British officer can gain has been won by Capt. James Byford McCudden, the star British airman, who has just been awarded the Victoria Cross, according to Associated Press correspondence. His other distinctions in the order of their award include the Distinguished Service Order, a bar to the Distinguished Service Order, the Croix de Guerre, Military Cross, bar to the Military Cross, and the Military Medal.

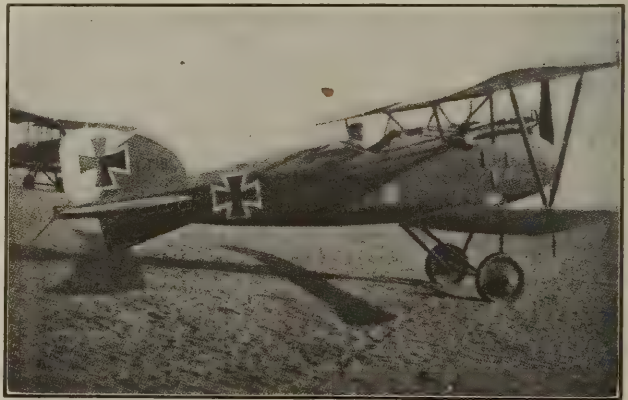
McCudden, who is now twenty-three years old, entered the British army as a bugler eight years ago. He went to France as a private in the original expeditionary force. Having had some experience in the air, he was pressed into service as an observer at Mons, and gave valuable information of enemy movements during the retreat. From a Sergeant he was promoted to a commissioned rank as an observer, and quickly won fame for his handling of a machine gun in aerial fighting. Since then he has had more than 100 fights without ever having sustained a wound.

Fifty-four German aeroplanes have been accounted for by Capt. McCudden. Of these, forty-two have been destroyed, nineteen of them on the British side of the lines.

"This officer is considered," says the official London *Gazzette*, "by the record which he has made, by his fearlessness, and by the great service he has rendered to his country, deserving of the very highest honor."

SWITZERLAND

The neutrality of Switzerland had been violated 586 times up to the end of January, according to an official announcement to-day. In 418 instances aviators were responsible. Switzerland has received little satisfaction for the protests made.



A German aeroplane captured by the British in Palestine. (British Official Phito)

Model Aerial Acrobatics

By Theodore Hodgdon

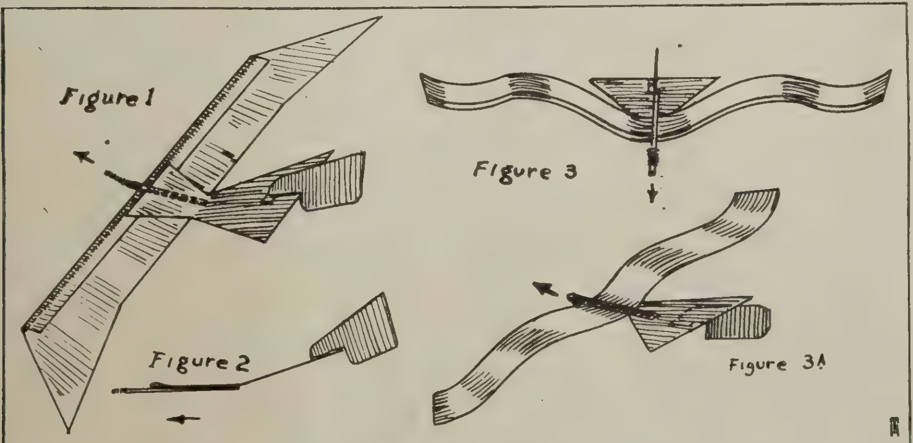
WIRELESS, clockwork, weights suspended so as to act as pendulums, and numerous other devices, have been used to compel models to do the various aerial "stunts," such as purposely side-slipping, looping-the-loop, tail-spinning and tail-sliding.

In the diagram below, Figure 1 shows a small paper glider which will prove a most interesting little exhibition model if made and thrown properly.

It is simply made of fairly stiff writing paper braced with wire, as indicated on the drawing with dotted lines. Wire wound around the longitudal brace serves to balance the model at a distance of one-half the chord. A wing spread of about seven inches and a length of 4½ inches (or less) will give good results. The tail, being set at a negative angle of about thirty degrees from the line of flight (as Fig. 2 shows) causes a suction or drag. Thus, when the model is held between the thumb and forefinger by the coiled weight, and thrown forward, it will loop-the-loop and glide gracefully to the ground.

Another stunt that this model performs successfully is the tail-spin, *i.e.,* it revolves about its tail, at the same time gliding toward the earth. To cause a tail-spin, warp the wings and throw the model in a bank. Invariably it will describe a wide curve and start downward, turning into a tail-spin. The reason of this, as near as can be determined, is that the wing warp starts the spin, but instead of revolving about the normal axis, as it should, the drag under the tail causes it to revolve about the tail.

Figures 3 and 3A show a model which possess remarkable stability in all directions. This model will perform the tail-slide successfully if dropped backwards (after making it slightly nose-heavy). After sliding backwards a few feet (it should be dropped from a roof or window-ledge) it will "nose down" and take a nose dive to earth. When dropped sideways it will right itself immediately, and if the nose is heavy will glide to earth. The elevator should be up in both cases.



Two of Theodore Hodgdon's paper gliders for performing "Aerial Acrobatics"

Tuning and General Adjustment of Models

TUNING up and adjusting models before flight forms, perhaps, the most interesting section of model aeroplaning since it is by overcoming the faults and endeavoring to elucidate the problems (exceedingly enigmatical at times), sometimes presented by a model's flight, that knowledge of the underlying principles of flight is attained. Mr. F. J. Camm, in *"Aeronautics"* gives some notes on the subject which should be of assistance to beginners particularly.

Firstly, then, as to launching. The tractor type requires to be launched slightly nose downwards, grasping the tractor in the left hand, with the right supporting the fuselage behind the center of gravity. The model is thrust forward at slightly *under* its flying speed, both hands being released simultaneously. It is good practice when testing a new model of this type to launch it down wind until the correct adjustment has been found, and, although it must be born in mind that this adjustment will not hold good for flying both with and up wind, a smaller negative angle being required on the tail for up-wind flying, it is much easier to tune a machine in this direction.

A twin screw pusher should be launched at a slight angle of elevation, holding the twin screws in the right hand, the left supporting the machine at an angel of four or five degrees, the model being thrust forward and released, as before. Here it may be remarked that it is far easier to launch a twin screw pusher when the propellers are revolving outwards.

Launching a model, however, after a time becomes purely a matter of knack—one unconsciously grasps the machine at the correct point and launches at the correct speed, so that we need not dwell upon this point further than to impress the importance of launching at the correct angle and speed.

We will assume that after launching a model of the tractor class it shows a strong tendency to fly in circles either to the right or left. This may be due (1) to torque, or the tendency of the screw to capsize the model in the oposite direction to which it is revolving, (2) to lack of alignment of the surfaces, (3) wrong adjustment of the rudder, (4) a warp in either the tail or mainplanes, (5) the propellers being out of pitch, and (6) (this cause of trouble is too often overlooked) the chassis heeling over in either direction and so causing the lateral centre of gravity to be out of line with the centre of the fuselage. If three or four degrees of ruddering fails to eliminate the first trouble, and provided that the model is correct with regard to the other possible causes, it may be concluded that the propeller is either of too large a diameter or too long in pitch, and a new propeller should be tried; but it can be taken as a general rule that the pitch should be made one and a half times the diameter, and this latter one-third the span, this rule referring to single screw models only.

(*To be continued*)

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Answers to Correspondents

R. F. C. (India).

There are several methods of exterminating mosquitoes. Perhaps the most effective and simple procedure is to obtain two blocks of wood (ash or spruce), each about 2 ins. square. Place the mosquito in the centre of one block, lay the other carefully on top, and place the whole in a press for about 7½ mins.

Designer (Farnborough).

No, it does not matter having the c.g. in the petrol tank, so long as a reliable filter is fitted.

Non-Stop (Claybury).

Yes, the war is still going on, and you are the 9849th correspondent who has solved the problem of perpetual motion.

Drachenflieger (Roehampton).

Rupert got his name for the same reason as the Blimp—because he looked it.

Fifty under (Bushmills).

To convert monoplane figures to biplane figures, use the following formula: $C_2H_5OH + H_2O$.

If the stagger is too pronounced, try more water with it.

Gordon (Kingussie).

Don't let that deter you. They are not worn in the R. F. C.

Pup.

All pupils are called "pups." We see nothing degrading in it. Don't worry, you'll grow up some day.

P. M. C. (Green Wood).

We suggest that you be governed by the two following "Air Laws":

Law I.—Taking the camber as being inversely proportional to the square of the slip-stream per foot-run, the formula

$$\text{Sin}^2\,\delta \int_0 \frac{\pi\, d\,\Theta \times 0.5\,\pi\,\xi\,C_{90}}{\triangle\,(\phi\,K)} + {}^3\sqrt{\psi} - \frac{P}{v} = A\left(\frac{l^e.m.O^n}{I}\right)$$

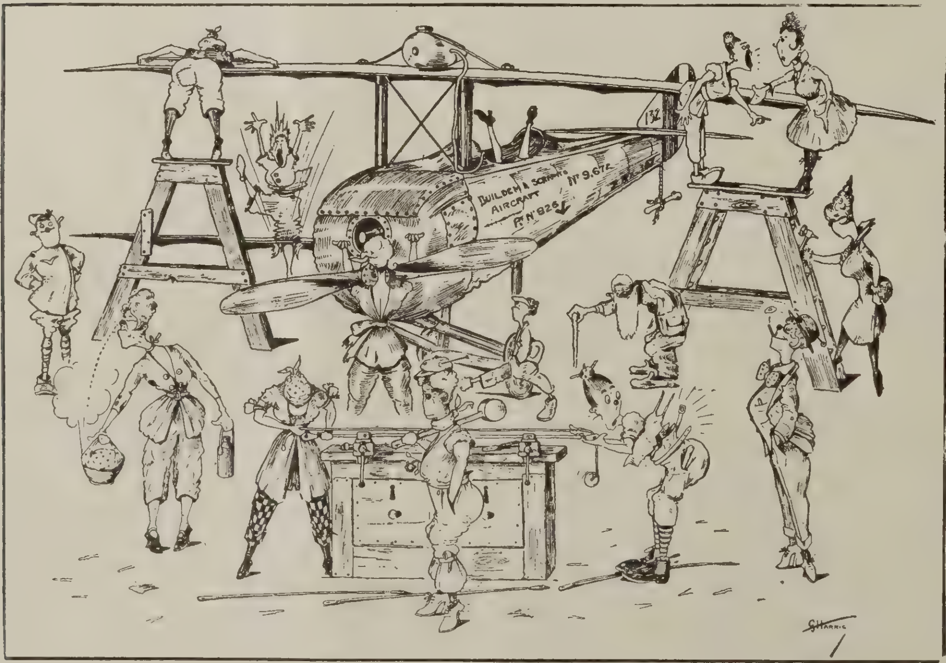
remains constant in perpetuity, always assuming that the conditions do not vary.

Law II.—Assuming staggered monoplane values for a given maximum range of uniform acceleration, the gyration of bifocal vortices approximate the empirical basis of the conjugate functions influencing the velocity potential of the modulus of elasticity resulting in the diminution of sustentation of all evanescent cyclic components of phugoids of negligible amplitude.

A Communication

Gentlemen:—We take great pleasure in informing you that the aeroplane mentioned in your last letter, which (by the way, is one of our most recent models) has shown most astonishing performances. It having attained an altitude of 18,000 in eight minutes, in the high speed test it surpassed our most sanguine expectation, easily drifting along at 308¼ miles per hour the low speed test was almost as remarkable, it seemed to stand perfectly still for several minutes than gradually rose, tail up, seemingly defying all the well known laws of gravitation, then without any apparent effort it performed a number of double loops, flip-flaps, cart-wheels??? Now, John, gratifying as the above appears it is not a circumstance compared to what we have under way, our new hover-clopter model 9 is a bird it will go so fast, that it will take two men to talk about it one to say HERE SHE COMES, the other, THERE SHE GOES, and as for speed, why I hate to talk about it as it sounds almost unbelieveable confidentially, we expect it to do in the neighborhood of 704 miles easy with the anti-gravitator attachment installed it should rise right smart, say 0¼ miles a minute.

G. J. C.



SCENES IN AN AIRCRAFT FACTORY

The Women's Assembling Shop

In the foreground, an unskilled laboress goes to work, skilfully combining the typical laborer's rig with the feminine allurement of a rose in her blouse and a projecting hat-pin. Behind her, a nattily attired worker, and one more carelessly clothed, prepares stays (or bracing wires) for the aeroplane, watched by a feminine equivalent of the juvenile—and exempted—shop steward. On the left, a hungry worker senses the odor of a full dinner-pail, to the amusement of an R. F. C. superintendent, who, doubtless out of regard for his charges, has fastened his tunic, womanlike, to the left.

—Courtesy The Aeroplane.

SAFE behind RESISTAL

"PROTECTEYES"

The Non-Shatterable Perfectly Transparent Glass in the best Aviator Goggles

The U. S. Bureau of Standards Report on Non-Shatterable Glass, says:—

"A 30 caliber bullet with a muzzle velocity of 2,700 ft./sec. was fired from a distance of 25 yards at a target supporting the glass. A bullet passing through type B glasses (this was RESISTAL) made a clean cut hole and produced numerous irregular cracks in each of the sheets of glass separated by the celluloid. These cracks were confined to a circular area of about 2 inches radius and the remainder of the plate remained practically uninjured. The cracks in the two plates of glass separated by celluloid in general, followed different directions, and did not register. This fact allowed the laminated plate to retain considerable rigidity even after it had been punctured. All the glass except a small area immediately around the bullet hole was firmly held by the celluloid."

"Ordinary plate glass, without celluloid covering, when struck by the bullet, flew into innumerable pieces and became a complete wreck.

"The relatively increased non-shatterability of laminated glass (this was RESISTAL) and its comparatively good transparency and rigidity even after puncture, give it great importance in devices for protecting the eyes and face."

(Signed by S. W. Stratton) Director.

B. S. Test No. 23004. Washington, D. C., March 25, 1918.

Thus proving the absolute fact that RESISTAL is Non-Shatterable and Transparent:—therefore SAFE

If you cannot get RESISTAL PROTECTEYES at your Dealer, write to Sole Manufacturers

STRAUSS & BUEGELEISEN, 438 BROADWAY
NEW YORK CITY

(*Continued from page* 357)

commercial diastofor in 500 cubic centimeters water at 140° F. (60° C.) for two hours.

(4) Wash thoroughly in hot water and then boil for one hour in 500 cubic centimeters distilled water and wash again.

(5) Dry in tared weighing bottles to constant weight.

(6) $$\text{Percentage sizing} = \frac{\text{loss in weight}}{\text{original weight}} \times 100.$$

(*i*) The fabric must not contain more than 3.5 per cent of sizing, as determined by the above method.

SELECTION OF TEST SPECIMENS.—5. (*a*) Samples for tests shall be taken from at least five bolts in each warp woven.

(*b*) The sample taken from a bolt shall be 1 yard long and the full width of the bolt; it shall be cut from the fabric at a point 10 yards from the end of the bolt.

(*c*) Test specimens for tensile tests, 12 inches long and 1¼ inches wide, shall be cut from each sample taken as shown in Fig. 1. Threads shall be pulled out from the sides of the test specimens until a width of 1 inch of woven fabric remains.

INSPECTION AND REJECTION.—6. The inspector shall mark all accepted material close to the end of each bolt with the official acceptance stamp. Rejected material shall be marked with the rejection stamp and shall not be resubmitted without the specific consent of the purchaser. The acceptance and rejection stamps shall be placed so that they do not injure the material, or, in the case of rejected fabric, so that the marking does not preclude the use of the material for other than aircraft work.

REPLACEMENTS.—7. All fabric that does not conform to this specification shall be rejected and shall be replaced by the manufacturer at his expense.

Specifications for Aeroplane Spar Varnish. (2V1 March, 1918)

GENERAL.—1. The general specifications, 1G1, shall form, according to their applicability, a part of these specifications.

COMPOSITION AND GENERAL PROPERTIES.—2. The material shall be the best long oil varnish, suitable for application on wood, "doped" linen or cotton, and metal, and must be resistant to air, light, water, and to washing with warm soap water. The manufacturer is given the greatest latitude in the selection of raw materials and in the process of manufacture in order to produce a product of the highest quality.

PHYSICAL PROPERTIES AND TESTS.—3. The material shall comply with the following requirements:

(*a*) It shall be clear and transparent.

(*b*) Its color shall not be darker than a standard color solution, made by dissolving 6 grams of pure powdered potassium bichromate in 100 cubic centimeters of pure concentrated sulphuric acid (specific gravity 1.84). Gentle heat may be used, if necessary, to secure a perfect solution of the bichromate. The color comparison will be made by placing the varnish and the standard color solution in clear, thin-walled glass tubes of the same diameter, 1.5 to 2 centimeters (⅝ to $\frac{13}{16}$ inch), to a depth of at least 2.5 centimeters (1 inch), and comparing the colors by looking through the tubes across the column of the liquid by transmitted light.

(*c*) It shall not flash below 35° C. (95° F.) in an open tester.

(*d*) The varnish shall be flowed on one side of a 10 by 15 centimeter (approximately 4 by 6 inches) panel of bright tin. The panels shall be approximately 0.3 to 0.4 millimeters (0.0125 to 0.0158 inch) thick (90 to 100 pounds weight of base metal per standard box of 112 sheets, 14 by 20 inches, No. 30 to No. 28 U. S. standard plate gauge), and shall be cleaned thoroughly with benzol. When the panel is held in a vertical position and maintained at a temperature of 21 to 32° C. 70 to 90° F.), the varnish shall set to touch at a point not less than 2.5 centimeters (1 inch) from the side or top edges of the film, in not more than 5 hours; and shall dry hard in not more than 24 hours to a clear, hard, glossy film. The panel shall then be allowed to dry for a further period of not less than 5 days and then be brought to a temperature of not less than 21° C. (70° F.) nor more than 24° C. (75° F.), and maintained at this temperature for not less than 15 minutes. The panel, with the varnished side on the outside, shall then rapidly be bent double over a rod 3 millimeters (⅛ inch) in diameter. The varnish film shall show no cracking or flaking at the point of bending.

(*e*) The varnish shall be applied to a basswood panel which has been filled with one coat of drop black in oil thinned with turpentine and drier, and allowed to dry for not less than 10 days before applying the varnish. It shall have suitable body to give proper brushing, flowing, and covering properties. The first coat of varnish shall be allowed to dry 48 hours, then lightly sandpapered, a second coat applied and allowed to dry 72 hours. The panel shall then be inclined at an angle of about 45°, and a gentle stream of cold tap water allowed to flow down the middle of the panel for 18 hours. After wiping off any deposits due to the tap water with a chamois skin, the varnish shall show no whitening, dulling, or other defects. A small stream of boiling distilled water shall then be allowed to flow down another portion of the panel for 20 minutes. The water shall be siphoned through a small glass tube, directly from a container in which it is boiling, onto the surface of the panel, in such a manner that there will be no appreciable lowering of the temperature of the water before it touches the varnish film. The siphon delivery tube shall be in a plane nearly parallel to the plane of the panel, so that the impact of the water will not tend to break the film. The varnish shall show no appreciable whitening and no more than a very slight dulling or other indications of marked deterioration, either when observed immediately after removing from the water or after drying for 2 hours.

[NOTE.—In general, results comparable to those given by the above method may be obtained by flowing one coat of varnish on duplicate panels of bright tin, thoroughly cleaned with benzol, allowing to dry 48 hours, and then immersing one of the panels in distilled water at room temperature for 18 hours and the other panel in boiling distilled water for 15 minutes. But the test on wood should be made in all cases where there is any doubt regarding the resistance of the varnish to water.]

(*f*) The varnish shall be applied in three coats to two unfilled panels of maple wood not less than 14 by 45 by 2 centimeters (5½ by 18 by ¾ inch), allowing 3 days for the drying of each coat. The first coat, after drying indoors for 3 days, shall be sandpapered lightly with No. 00 sandpaper before the application of the next coat. The second and third coats shall not be sandpapered or rubbed, and the duplicate panels shall be exposed outdoors, 45° to the vertical, facing south, 3 days after the application of the finishing coat. The backs and edges of the panels shall also be varnished with three coats of the same sample, but for these surfaces the details of the method of application as given need not be adhered to, and the effects of exposure on these surfaces will not be considered. In the test, the varnish shall show satisfactory durability and weather-resisting properties. In cases when the award of a contract can not be delayed for the results of the exposure test, award may be made on the basis of the other requirements, but a varnish of any specific brand which does not prove satisfactory in the exposure test may be omitted from consideration in future awards, and a preliminary submission of samples for making exposure tests may be called for.

balanced in 20 minutes

For the tedious guesswork of former methods the Carwen Dynamic Balancing Machine substitutes a precise process of measurement.

Five minutes suffice to determine the exact *plane* of running unbalance and its *amount.*

Five minutes more suffice to convert that measurement into weight of metal to be removed at definitely-known points, and to remove it by drilling.

The preliminary static balancing, with suitable appliances which we furnish, takes no more than ten minutes.

Total, 20 minutes,—and many hours of someone's time released for other duty!

Only ordinary skill required. We gladly demonstrate.

Need of Aerial Supremacy Pointed Out by General Verraux

GROWTH

THE future mammoth growth of the airplane industry is indicated by such an organization as the Wright-Martin Aircraft Corporation now expanding rapidly under the leadership of men of known ability.

This company, originators of the basic aviation patents, has kept abreast of progress not only in the manufacture of airplanes, but also in the production of the famous Hispano-Suiza engine.

It is essential that executive ability of the highest order, as well as highest specialized manufacturing ability be combined in an industry whose future stands upon no precedent of the past.

NEED OF AERIAL SUPREMACY POINTED OUT

By A FRENCH GENERAL

IF the Allies cannot break the German lines they can leap them, and victory will come to the Entente through the air, General Verraux has declared.

In reviewing the possibility of two practically evenly balanced armies being able to break the other's line by force of arms, General Verraux declared that supremacy must come through the air.

"Modern armies must place their hopes in their airmen," he stated. "The victory which Germany believed always just within her grasp has been snatched away by the French, British, Italian and American airmen.

"With our air squadrons we have shattered traditions of former wars—we have broken the military formulas of yesteryear—when strategy won battles.

"If we cannot break through the enemy lines we can leap them, as proved in recent battles."

DIRECTOR OF AIRCRAFT PRODUCTION APPOINTED

ON April 24th Secretary of War Baker announced the appointment of Mr. John D. Ryan as Director of Aircraft Production for the Army, Brigadier-General William S. Kenly as chief of the newly created Division of Military Aeronautics, and Mr. W. C. Potter as chief of the Equipment Division.

The official announcement reads as follows:

"Mr. John D. Ryan has accepted the directorship of aircraft production for the army.

"A reorganization of the Aviation Section of the Signal Corps has been also effected, of which the principal elements are as follows:

"General Squier, as Chief Signal Officer, will devote his attention to the administration of signals; a division of Military Aeronautics is created, under the direction of Brigadier-General William L. Kenly. The Aircraft Board, created by Act of Congress, remains an advisory body as it has been in the past, with Mr. Ryan as its chairman. This arrangement is made with the entire concurrence of Mr. Howard Coffin, who remains a member of the Advisory Commission of the Council of National Defense, and will render assistance and counsel to the Aircraft Board and Mr. Ryan.

"The Division of Military Aeronautics will have control of the training of aviators and the military use of aircraft. The exact division of function in the matter of designing and engineering will be worked out as experience determines between the Division of Military Aeronautics and the Division of Production.

"This announcement involves no change of personnel in the present Equipment Division of the Signal Corps, of which W. C. Potter is chief, and will continue under his direction."

Mr. John D. Ryan, one of the country's foremost business organizers and industrial mobilizers, is best known for his work in connection with the world's greatest copper corporation, the Anaconda Copper Company, of which he is president. In the last year, however, Mr. Ryan has been continuously in the Government service, first as Director-General of Military Relief of the Red Cross and later as an advisor of the War Industries Board.

Brigadier-General Kenly, it will be remembered, was the first officer of the line to volunteer to take the course in aeronautics in the summer of 1916. He was also one of the first officers sent to France when the United States entered in the war and while in charge of the Air Service there did a great deal of flying and gained practical knowledge about aeronautics which the former heads of the Air Service home never gained. For this reason it is believed that there will be no further delay on deciding on types of aeroplanes to be manufactured after the General assumes his new duties.

Mr. William C. Potter entered the service of the Government on January 2d, in the equipment division of the Signal Corps, and is thoroughly familiar with the present perplexing aircraft situation.

Men Selected Generally Approved—New Legislation Required to Give Them Power

The selection of Mr. Ryan, General Kenly and Mr. Potter to manage the new program is generally approved, but it is being realized that their effectiveness depends on the organization and funds placed at their disposal. At present the new appointees have neither the organization nor the funds which are absolutely necessary to make and carry out a program necessary to build our aerial forces to the size required to beat Germany.

In making these appointments President Wilson went as far as he could under the existing legislation.

To provide the necessary organization and to make the change effective, Senator Wadsworth, on April 25th, introduced the following amendment to the Overman Bill, which was adopted by the Senate:

Sec. 3. That the President is further authorized to establish an executive agency which may exercise such jurisdiction and control over the production of aeroplanes, aeroplane engines, and aircraft equipment as in his judgment may be advantageous, and further, to transfer to such agency, for its use, all or any moneys heretofore appropriated for the production of aeroplanes, aeroplane engines, and aircraft equipment.

Senate Report of Delay in Aircraft Program Brings Severe Condemnations

The publication of the Senate report, published in AERIAL

Age for April 22d, showing the great delay in the aircraft program, and the reports of the apparent deplorable conditions were made in public charges by the investigators appointed by the President, caused consternation throughout the country and brought severe condemnations of Major-General Squier's administration of the air services.

On April 26th the New York *Times* said editorially:

AT LAST!

A long-suffering people will applaud the War Department's detail of General George O. Squier to "devote his attention to the administration of signals." As the genius of army aviation he has been a lamentable and exasperating failure. He was to produce great numbers of aeroplanes and train a host of aviators, thus insuring supremacy in the air for the Allies in France and putting out the eyes of the enemy. The opportunity to organize victory knocked at the door of the wrong man. It may always remain a mystery why George Owen Squier was selected to do one of the biggest things of the war. It is true that he became the head of the Signal Corps two months before the United States entered the conflict. If there was any other reason for giving him the authority to create an air fleet for an army greater than Wellington commanded at Waterloo it has not been divulged.

General Squier had no recognizable fitness for a task that called for executive ability, intimate knowledge of industrial conditions, and facility for dispatching business quickly. He knew nothing about spending vast sums of money. He did not know men. He did not have the vision of a pioneer or a promoter. He was simply a Signal Service officer interested in electro-chemical effects due to magnetization, the polarizing photo-chronograph, ocean cabling and multiplex telephony, and it is not of record that he was in any degree an authority on practical aeronautics. He had been Military Attaché at London before the war and danced well. No mystery is more inpenetrable than that surrounding the designation of General Squier to build myriads of aeroplanes and train legions of flying men in record time at an expense of billions of dollars. His failure to make even a good beginning of the job was tragical for the country, and it was cause for jubilation in Germany.

The enterprise had creeping paralysis from the first. It never straightened up and got to its feet. Hailed as a precocious and lusty child, it did not leave the cradle. Credulous and misguided officials passed the word that America was to have so many thousand aeroplanes by such a date, and those of any use to a field army could be counted on the fingers and thumbs when the time of performance came round. And then it was thought necessary to cover up the scandal, for the collapse of efficiency was nothing else, by solemn reviews of incalculable difficulties and unexpected obstructions that the War Department had had to contend with, ending with the assurance that the "peak of production" was now in sight and all would soon be well. But the performance could not have been more disappointing if the Germans had had a hand in it. In the history of American preparations for war there has been no worse exhibition of inefficiency, cross-purposes, and impotence than that made by the Signal Corps in aeroplane construction.

But the nightmare is over at last. General Squier returns to his signals and Mr. Howard E. Coffin ceases to be Chairman of the Aircraft Board with his "entire concurrence," to quote from Secretary Baker's reorganizing order inspired by the President. In place of General Squier as builder of the air fleet the country will have a representative of big-brained business, Mr. John D. Ryan of Montana, who is appointed Director of Aircraft Production for the Army, and Brig. Gen. William L. Kenly, U. S. A., as Chief of Military Aeronautics, succeeding Mr. Coffin, who has not been a satisfactory prophet. The country will now have well-directed hard work and very little talk from those responsible for army aviation. The "peak of production" may not be in sight, but it will soon loom up.

Thus is the berated investigating activity of Senator Chamberlain and his courageous associates vindicated. The American people owe them a debt of gratitude beyond words. We should think that those who have aspersed their patriotism would ask that their words be forgotten. As the result of hearings before Congress committees, the Ordnance Bureau, the Quartermaster's Department, and the Shipping Board have been reorganized, and to bring order out of conditions approaching chaos and to do big things in a big way Stettinius, Schwab, and Ryan have been called in. It recalls Opie's reply to the question how he mixed his colors: "With brains, Sir!"

The following are excerpts from the scores of editorials which have appeared in the newspapers throughout the country:

THE AIRCRAFT FAILURE

(*The Oklahomian*)

The senate military committee declares our aircraft program to be "gravely disappointing," and recommends "drastic reorganization of the production machinery." If the committee's statements of what has not been accomplished are statements of fact, the expression "gravely disappointing," is weakly inadequate, and the recommendation of "drastic reorganization" will be demanded by public opinion.

The production program of aeroplanes, which through fraudulent publicity the public had been misled to believe was going forward splendidly, is a myth, the committee says. It is alleged that 12,200 cadets, sent to France, England and Italy last year, have not been able to complete their training because we have not furnished them with planes. It is said that but 450 of those cadets have been graduated as fliers. The question of bringing those boys back to the United States, the committee avers, is now under advisement by the signal corps. There are twenty aviation schools in the country now, with a capacity of 3,000 cadets. Of those, 1,926 have been commissioned as reserve military aviators, but very few have received advanced training.

In the production of Liberty motors the same languor, not to say inertia, is charged. Of the 22,500 ordered "only twenty-two have been completed for the army, 142 for the navy, and four have been shipped overseas." Moreover, the glowing press notices of this motor are sadly discounted. The senate military committee declares that the "Liberty motor is not designed for and cannot be used in the swift, single-seated fighting machines." Its utility is restricted to the bombing machine.

The failure in aircraft production and management as portrayed by the senate military committee seems too complete to be credible. But if this assessment is correct or if it even approximates the truth, the official heads responsible for it should be cut off instantly—as instantly, for example, as England has just recalled General Gough for his failure at the front—and new methods should be instituted and new men chosen for this work. The tradition that the accused is entitled to his day in court, may be dismissed in this instance. The nation, in this crisis, is concerned only with the facts. Let the facts be determined and let action follow forthwith.

IT IS ABOUT TIME!

(*Cincinnati Times Star*)

On Tuesday the New York *World* printed an interview with W. A. Morgan, recently Vice-President and Production Expert of the Curtiss Aeroplane Company. His remarks constitute a vivid indictment of the lack of settled purpose which has so outrageously delayed work on our aeroplane programme.

Mr. Morgan tells how his concern was blocked in its effort to build battle planes by the inability of the Aircraft Production Board to settle upon a fixed type of machine.

"The changes ordered in the Bristol Fighter," says Mr. Morgan, "were literally hundreds. The first great difficulty was about a motor. The Board decided primarily to use the Liberty eight-cylinder (which, as is now known, has been entirely discarded); but they found that would not fit in the Bristol. Then they decided upon a certain type of French motor and then upon another type of French motor of greater power. These changes, of course, caused important changes in the machine, its balance and so on.

"Then they could not seem definitely to decide upon what sort of machine gun to use. They would order one kind, then another, then revert to the first again. This necessitated alterations in the machine proper and alterations in the gun mounts. Then a certain sort of instrument would be ordered, abandoned, and another type ordered and abandoned. We never knew where we were—and here was a force of 11,000 literally straining at the leash, ready to give all their strength and skill to the job of fast production.

*"It is no trick to turn out aeroplanes by the thousands. * * * But we can't fight with designs; we have to fight with actual planes."*

Washington tells us that the aeroplane situation is beginning to improve; that it will not be long now before we are turning out battle planes and sending them to Europe. It is about time. If the United States can build a million and a half automobiles a year, it surely can build enough fighting aircraft to break up that control of the air over the American sectors in France which the Germans now possess!

THE NEWS OF THE WEEK

Brig.-General Kenly on Air Tour of Flying Fields

Brigadier General William S. Kenly, the newly appointed chief of the Division of Military Aeronautics, who has been flying from aviation camp to aviation camp inspecting the camps, familiarizing himself with existing conditions and testing the flying qualities of aeroplanes, arrived at Mineola, April 27, having made a non-stop flight from Washington.

General Kenly started from the Capitol at 1:45 in the 450 h.p. Italian Caproni biplane, which has been flying daily in New York, Philadelphia and Washington for the past month to create interest in the Liberty Loan. With the General was his son, Lieutenant Kenly. Captain Silvio Resnati, the famous Italian aviator, was the pilot, and Captain Hugo D'Annunzio, the noted Italian aeronautic engineer, son of the famous poet, was the reserve pilot.

They started from the Polo Grounds, a few minutes from the White House, and left the Capitol at a height of 3,000 feet. Then they rose to 6,000 feet to get above the low clouds which were below them for most of the way. The wind was against them and cut down the speed of the machine considerably. They arrived at Mineola at 5 o'clock, having taken three hours and fifteen minutes to cover the distance between the Capitol and New York.

The General, as well as Captains Resnati and D'Annunzio and Lieutenant Kenly said it was a pleasant flight throughout. On April 28, General Kenly with the other officers flew from Washington to Philadelphia and back to Washington to test the flying qualities of this type of Caproni warplane, which is being used extensively by the Italians for bombing raids, and to make a quick aerial survey of the landing place selected at Philadelphia for the military aeroplanes that will carry the mail in a few weeks between New York, Philadelphia and Washington. The trip was made in three and a half hours, making a total of close to seven hours of flying General Kenly has had in two days.

Signal Corps Requires Draftsmen

In a statement authorized by the Civil Service Commission, the following appears:

"The Signal Corps of the Army is short of aeronautical mechanical draftsmen. The Navy has an unlimited number of places for draftsmen of various kinds and for a long list of technical workers.

Government Financial Co-operation

The War Finance Corporation which has been established by Congress to finance corporations doing war business will soon be ready to commence operations. Section 9 of the text of the Act creating the War Finance Corporation is as follows:

Sec. 9. That the Corporation shall be empowered and authorized, in exceptional cases, to make advances directly to any person, firm, corporation, or association, conducting an established and going business in the United States, whose operations shall be necessary or contributory to the prosecution of the war (but only for the purpose of conducting such business in the United States and only when in the opinion of the board of directors of the Corporation such person, firm, corporation, or association is unable to obtain funds upon reasonable terms through banking channels or from the general public), for periods not exceeding five years from the respective dates of such advances, upon such terms, and subject to such rules and regulations as may be prescribed by the board of directors of the Corporation. In no case shall the aggregate amount of the advances made under this section exceed at any one time an amount equal to twelve and one-half per centum of the sum of (1) the authorized capital stock of the Corporation plus (2) the aggregate amount of bonds of the Corporation authorized to be outstanding at any one time when the capital stock is fully paid in. Every such advance shall be secured by adequate security of such character as shall be prescribed by the board of directors of a value at the time of such advance (as estimated and determined by the board of directors), equal to (except in case of an advance made to a railroad in the possession and control of the President, for the purpose of making additions, betterments or road extensions of such railroad) at least one hundred and twenty-five per centum of the amount advanced by the Corporation. The Corporation shall retain power to require additional security at any time. The rate of interest charged on any such advance shall not be less than one per centum per annum in excess of the rate of discount for ninety-day commercial paper prevailing at the time of such advance at the Federal reserve bank of the district in which the borrower is located.

Major Thaw an "Ace" with 5th Air Victory

Paris, April 24.—Major William Thaw, commanding the Lafayette Flying Corps, is now counted among the "aces" in aviation in France, having brought down his fifth adversary and a captive balloon on the same day, April 20.

Major Thaw within the past month has accounted for three opponents in aerial encounters.

A dispatch from Paris relating to the exploits of American aviators says:

"The *Petit Parisien* gives dates concerning the most recent exploits of the American aviators. On April 20 Major Thaw, commander of the Lafayette Squadron, won a splendid double victory, bringing down in turn a Drachen and a monoplane. These two victories permit him to be enrolled among the prize aviators.

"Since he assumed the command of the glorious unit, he seems to have particularly distinguished himself. Major Thaw evidently wishes to set an example, and many of his compatriots will take their places within a short time among the air champions, notably Captain Biddle, Lieutenant Baer (nine victories, four of which were official in the space of forty-three days), and Sergeant Bylies. Meanwhile two Americans already have taken precedence of them, Major Lufbery and Major Thaw."

Lufbery Brings Down His 18th German Aero

Paris, April 25.—Major Raoul Lufbery, of Wallingford, Conn., destroyed his eighteenth German aeroplane on April 23rd, and Lieutenant Paul Frank Baer, of Mobile, Ala., brought down his fifth German machine on the same day, thus becoming the latest American ace. Besides the machines he is officially reported to have destroyed, Baer is believed to have brought down two other German machines. His seven victories have been scored in the past six weeks.

The semi-official count of victories won by American aviators in the French and American service now shows a total of forty during the past two months.

Two Fly from Mineola to Washington and Return in Day

Announcement was made at the Aero Club that a new American record for cross-country flying with two flyers was set on April 23 by Major Joseph Tulasne, the chief of the French aviation mission to the United States, and Lieutenant George Flachaire, the French ace, who flew to Washington for lunch and returned to New York for dinner. The flyers started from the Mineola field at 9 o'clock and they landed back on the field at 6 o'clock the same night.

It was the first aero round trip between Mineola and Washington and the longest distance covered in the United States in one day by two men in one machine. It was announced the machine made more than 500 miles.

The two famous French birdmen made the flight in a Breguet bombing biplane equipped with a 300-horsepower Renault motor. Before making their start they circled over Long Island in order to attain a height of 8,000 feet. They arrived at the Capitol at quarter past 12 o'clock. They landed on the Polo Ground. After having lunch they started on their return trip at 3 o'clock. They arrived at Mineola three hours later. Both flights were made at a height of about 6,000 feet.

Lord Rothermere Quits as British Air Minister

London, April 25.—Lord Rothermere has resigned as Air Minister and President of the recently organized Supreme Air Council.

It is expected that Sir William Weir, Director General of Aircraft Production, will succeed him.

In a letter to Prime Minister Lloyd George tendering his resignation Lord Rothermere explained that the burden of his work and responsibility has seemed crushing in consequence of his great distress of mind and body caused by illness

Scene at a Naval Station, "Somewhere in America," showing fifteen planes on beach departing and arriving.

© Committee on Public Information.

and his "second tragic loss in the war." His second son, Lieutenant Vere Sydney Harmsworth, was killed in battle in November, 1916, and his eldest son, Lieutenant Harold Alfred Harmsworth, was killed in action last winter. Lord Rothermere wrote the Premier that he had felt it his duty to remain at his post until the two air services, army and navy, were consolidated, which has now been successfully accomplished, and recently he had hoped to continue in office, but this has been prevented by recurrence of illness.

Premier Lloyd George replied that he received the resignation with deepest regret. He eulogized Lord Rothermere for his work, expressed sympathy on account of his losses, and concluded: "I am authorized by my colleagues to state that they share fully the views expressed in this letter."

Lord Rothermere's resignation surprised the political world. It had been announced that illness made it impossible for him to reply in the debate which Lord Sydenham intended to begin last Tuesday in the House of Lords in regard to the resignation of Major General Trenchard as Chief of the Air Staff and Major General Sir David Henderson as Director General of Military Aeronautics, but no one outside the Cabinet knew that Rothermere's condition was so serious as to make his resignation necessary.

Lord Rothermere has been criticised severely by some newspapers for running counter to General Trenchard and General Henderson, both of whom have done great work for the air service. This criticism grew more severe when it became known to-day that the financial adviser of the Air Ministry, who joined it at Lord Rothermere's request, also had resigned owing to disagreement with his chief's policy. What the differences were has not been disclosed.

Seaplane Makes Record on Flight

San Diego.—A seaplane, piloted by Malcolm Loughead and carrying three passengers, arrived here at 12:23 on April 12.

The F-1 left Santa Barbara at 9:21 this morning and the estimated distance of 190 miles between that city and San Diego was therefore covered in exactly three hours and two minutes, a speed of approximately 63⅓ miles an hour. The big seaplane was first sighted over Point Loma and within a few minutes alighted on the surface of San Diego Bay a short distance from the United States army aviation station at North Island. At 12:23 the seaplane reached the North Island landing and was hauled ashore by army men in waiting. According to Pilot Loughead, the trip was made without incident, although during the latter part of the trip head winds were met with which retarded the speed of the aircraft.

The seaplane was constructed by the Loughead Aircraft Company, of Santa Barbara, Cal.

Miss Stinson and Miss Law Have Aeroplane Race

Miss Katherine Stinson and Miss Ruth Law will have an aeroplane race at Sheepshead Bay Speedway on Memorial Day, May 30, on the occasion of the Harkness Handicap 100-mile race.

Flying Over Washington

Colonel Lee, of the British flying mission, in an Avro fighting plane, and Captain Silvio Resnati, the Italian airman, entertained Washington with some remarkable exhibition flying during the past week. On April 24 both fliers were in evidence.

While Colonel Lee slipped, slid, looped, twisted, turned, dodged, fell, dived and spun over the Potomac Park Aerodrome and the downtown section of the city in his trim little machine, the Italian guided his huge engine of death in great circles and figure eights all over the city, barely skimming the house and tree tops, and at times seeming so close to them that disaster apparently was inevitable.

Captain Resnati did stunts while the British tank Britannia entertained huge throngs in Rock Creek Park. Circling over the park, he dropped thousands of Liberty Loan leaflets, while the crew of the tank was putting that engine of destruction through its war paces. It was a startling combination show of the new war as waged on land and in the air.

Miss Ruth Law dropped Liberty Loan literature over Washington on Liberty Day.

Major-General F. H. Sykes, who has been appointed Chief of the London Air Staff, replacing Major-General Trenchard, retired
© Press Illustrated Service.

Mr. Baker Tells Senate Committee of His Trip

Information gathered by Secretary Baker on his recent visit to Europe was given to the Senate Military Affairs Committee on April 24. Like the hearing yesterday before the House committee, to-day's conference was behind closed doors, and several Senators not on the committee attended.

Secretary Baker was with the committee less than an hour. Plans for expansion of Army or draft legislation were not discussed. The Secretary said he was not yet ready to present those subjects, but after the hearing he took occasion to deny reports that President Wilson is "holding up" the Army expansion program.

Nice-Paris-London Air Line

Washington, April 26.—An aerial line between Nice, Paris and London is to be established soon, says a dispatch to-day from Rome. Italy has started an enormous industrial expansion looking to the development of aviation, according to an Associated Press dispatch.

Aircraft Board Pays Tribute to Bolling

Washington, April 26.—Resolutions in recognition of the distinguished service given to the nation by Colonel Raynal C. Bolling, killed in France, were made public to-day by the Aircraft Board, as follows:

"Colonel Raynal C. Bolling, Signal Corps, United States Army, was killed by the enemy on a battlefield in France in the performance of his duty. Colonel Bolling was a member of the Aircraft Production Board and rendered distinguished service to his country as a member of a mission to Europe to negotiate important military matters between the United States and Allied Governments. His high motives, brilliant attainments and unfailing devotion rendered his work of inestimable value to his country and deepens the sense of personal loss to the members of this board.

"Be it resolved, therefore, that this statement be spread upon the minutes of the board, and a copy of the same be sent to his family as a brief memorial to the brave gentleman and gallant soldier, Raynal C. Bolling, Colonel, Signal Corps, United States Army, killed in action in the defence of his country and in the cause of liberty among the nations of the world."

A German Fokker monoplane exhibited at "Liberty Land" at the 69th Regt. Armory, New York City

339 Enemy Aeroplanes Downed By Lafayettes

WASHINGTON, April 26.—American aviators in France had downed 339 enemy planes from the time the United States entered the war up to March 8, according to unofficial reports from France.

Many more than this number were actually downed, but were not counted officially for various reasons.

Sir Weir Head of British Air Force

LONDON, April 26.—Sir William Weir has been appointed Minister of the Air Forces in succession to Lord Rothermere, brother of Lord Northcliffe, who resigned.

Sir William Weir has been Director-General of Aircraft Production. He was born in 1877, and has been in the aeronautical service since last year. Formerly he was Scottish Director of Munitions.

Italian Sets New World's Record at Washington

WASHINGTON.—Sergeant Gianfelice Gino, of the Italian Flying Corps, established on April 26th what is said to be a new world's record for speed when he flew from Langley Field, Hampton Roads, Va., to Washington in a Spa fighting plane in one hour. The distance is 145 miles. He left Hampton Roads at 12:30 and arrived in Washington at 1:30.

German Aeroplanes Exhibited at 69th Regt. Armory

Numerous war exhibits, including three captured German aeroplanes, are to be seen at "Liberty Land," at the 69th Regiment Armory, New York City. These attractions are displayed under the direction of the Liberty Loan Committee, the United States Treasury Department, and the War Commissions of France, Great Britain and Italy.

The most interesting machine is a large Aviatik biplane, a German Type C "General Utility" aeroplane which is in a fair state of preservation. It is one of the more recent machines, having a 6-cylinder 22 H.P. Benz engine.

The remains of an Albatros Hydro-aeroplane show the effects of a severe "straffing," but an idea of the construction can be formed from its inspection. A Fokker monoplane, captured by the British, is also shown. Some of the fuselage fabric is torn off, revealing the interior framework which is entirely of steel tubing with welded joints. The fact that this monoplane at one time held unquestioned mastery of the air in the sectors at which it first appeared, makes it a prominent part of the exhibit.

The display of aerial bombs,, part of a Zeppelin framework and various types of machine guns attract the attention of those interested in war in the air. Among the hundreds of official war photographs covering the four walls of the armory are many avation pictures.

"Liberty Land" was formally opened to the public on April 13th, and continue until May 4th. The 69th Regiment Armory is on Lexington Avenue at 25th Street, New York City.

Navy Flying Uniform

Changes in Uniform Regulations, U. S. Navy,
1913. *No. —, April* 1, 1918.
Navy Dept., Office of Naval Operations,
Washington, D. C.

The following service flying uniform for officers detailed for aviation duty and officers of the Naval Reserve Flying Corps is prescribed. This uniform will also be worn by student officers with the exception as enumerated in paragraph under student officers. This cancels Changes in Uniform Regulations, U. S. Navy, 1913, Nos. 11, 12 and 14:

WINTER FLIGHT SERVICE

Coat.—To be of same pattern as white service coat, Uniform Regulations, U. S. Navy, except that on the front there shall be four patch pockets of the same material as the coat, the two upper pockets being on the breast on each side, 7 inches deep and 6 niches wide, in side measurements, and vertically pleated down the center by a pleat 1½ inches wide, the top of these pockets being on a horizontal line 1 inch below the points of the shoulder; the upper pockets shall be closed by flaps of the same width as the pockets and

THE NEW PERSONNEL IN CHARGE OF AIRCRAFT PROGRAM

As related on the editorial pages of this issue Aerial Age, important changes have been made in the departments responsible for the aeronautic branch of our army services.

Mr. John D. Ryan

Mr. John D. Ryan, the new Director of Aircraft Production, one of the country's foremost business organizers and industrial mobilizers, is best known for his work in connection with the world's greatest copper corporation, the Anaconda Copper Company, of which he is president. His reputation as a leader in the financial world was founded chiefly on the remarkable managing ability displayed in the formation of the Anaconda company, though his interests in a string of banks and in Western railroad electrification work are equally important.

John D. Ryan, the new head of Aircraft Production

In the last year, however, Mr. Ryan has been continuously in the Government service, first as Director General of Military Relief of the Red Cross and later as an adviser of the War Industries Board. He is ranked as the leading copper authority in the United States and at the time Daniel Willard resigned the chairmanship of the War Industries Board, Mr. Ryan was mentioned as his successor.

His Red Cross work was voluntary, and he had complete supervision of maintaining the base hospitals at home cantonments and in military camps abroad.

The story of the rise of the latest industrial executive to command one of the important branches of military equipment dates back to days when corporations were viewed with popular suspicion of governmental disapproval, and his elevation to the presidency of the old Amalgamated Copper Company in 1909, of which he had been managing director, marked the turning point in the stormy career of this gigantic corporation. Under the regime of H. H. Rogers, whom he succeeded, the Amalgamated company was classed as the copper octopus, and one of Mr. Ryan's first official acts was to submerge the muckraked corporation in the concern now known as the Anaconda, which at that time was a subsidiary of the Amalgamated.

His experience in the mining regions of Montana, where he had managed the local affairs of the Amalgamated Copper Company before coming East, fitted him for the task of revamping the greatest copper mining company in the United States.

Mr. Ryan's ability for efficient organization expanded beyond the realm of the copper industry and a few years ago he undertook the management of the Montana Power Company, which has developed into a power corporation supplying current for more than 500 miles of railroad in the West.

Through investments in mining enterprises in South America, notably in Chile, Mr. Ryan became heavily interested in a number of properties there, which have since helped swell the Anaconda's profits in recent years.

In addition to his activities in copper corporations, his banking and railroad connections include directorships in the following: Guaranty Trust Company, Mechanics and Metals National Bank, Emigrant Industrial Savings Bank, American Surety Company, Chicago, Milwaukee and St. Paul Railway, Montana Power Company, and the United Metals Selling Company.

Mr. Ryan was born at Hancock, Mich., October 10, 1864, and when 32 married Miss Nettie Gardner of his native town.

Brigadier-General Kenly

Brig. Gen. William L. Kenly, who is to head the new division of military aeronautics, has been attached to Gen. Pershing's staff in France and only recently returned to the United States. He will look after the training of aviators and the military use of aircraft. The personnel of this division will be announced in a few days.

Brig. Gen. Kenly was the first officer of the line to undertake the course in aeronautics in the summer of 1916, and during the past few weeks he has been making a tour of the aviation field by air route, becoming familiar with existing conditions and getting an opportunity to study the various types of aeroplanes and their respective merits. His sound, practical knowledge well qualifies him for the gigantic task with which the President has entrusted him.

William C. Potter

Mr. William C. Potter is head of the Equipment Division of the Signal Corps. He comes from Massachusetts, colonial stock, the family having settled in Ipswich in 1635. One of his antecedents was John Potter, a lieutenant in the Revolutionary Army. His father, Edwin Augustus Potter, a former president of the Continental and Commercial Bank of Chicago, now resides at Lake Geneva, Wis.

Mr. Potter is a graduate of the Greenwood Avenue Public School of Chicago, the Chicago Manual Training School and the Massachusetts Institute of Technology in 1897. He holds the degree of M.E. and A.B.

In 1898 he entered the employment of the Liberty Bell Gold Mining Co. of Telluride, Col., going the next year to Libby Creek, Mont., as a mill foreman. Then he entered the employment of the Atchison & Sante Fe Railway as a mining engineer in the Industrial Department.

In 1902 he became a member of the firm of Dickman, McKenzie & Potter of Chicago, but in 1903 he took the management of the Guggenheim Exploration Co. in the City of Mexico. From 1905 to 1911 he was general manager of the Southern Department of the American Smelting & Refining Co., with headquarters at Aguascalientes, Mexico.

William C. Potter, in charge of the Equipment Division of the Signal Corps

Next he was made president of the Intercontinental Rubber Co. of New York. He resigned to accept the first vice-presidency of the Guaranty Trust Co. of this city in 1812, relinquishing this position in 1916 to join the firm of Guggenheim Bros., 120 Broadway. He became president of the Braden Co. and vice-president of the Chile Exploration Co.

On January 2, 1918, he entered the service of the Government in the Equipment Division of the Signal Corps, and, naturally, is familiar with the present perplexing aircraft production situation.

Brigadier-General William L. Kenly, in charge of the Division of Military Aeronautics

Mr. Potter was married in Chicago in 1902, his bride being Miss Caroline Morton, daughter of the late Paul Morton, former Secretary of the Navy, and later president of the Equitable Life Assurance Society. They have two daughters, Jean and Charlotte. Charles H. Sabin, president of the Guaranty Trust Co. of this city, is his brother-in-law.

Among his clubs are the Links, Metropolitan, National Golf Links, Shinnecock Hills Golf, Racquet and Tennis, Piping Rock, Rocky Mountain, Bankers' Club of America, Recess and the Club of Royal Game.

By his associates Mr. Potter is regarded as eminently qualified to carry out successfully any undertaking to which he may be assigned by the Government.

Aeroplanes at Columbia for New War Activity

New York, April 27.—Three aeroplanes marked with the French tri-color, seen in a quiet corner of the Columbia University campus, were the first evidences of a new war activity of the university, the establishment of a United States Signal Corps Radio School. A statement announcing the opening of the new school was issued by Dr. G. B. Pegram, acting dean of the faculty of applied sciences.

Armed guards kept back a crowd which gathered near the machines, which are Curtiss training aeroplanes with the motors removed. They will serve as "dummies" for practice in aerial wireless by men of the Signal Corps Radio Schoo.l

One hundred and fifty students are expected to arrive soon to begin training in the radio school. They will be taught the use of wireless apparatus in aeroplanes and other branches of signal work.

NOMENCLATURE FOR AERONAUTICS

By the NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS

FOR the information of those interested in aeronautics the following nomenclature has been prepared as a guide, with a view to eliminate the duplication of terms, the erroneous use of terms, and confusion of terms, and to define the principal terms which have come into use in the development of aeronautics. In the preparation of this nomenclature only those terms have been defined which are peculiar to this subject.

Aerofoil: A winglike structure, flat or curved, designed to obtain reaction upon its surface from the air through which it moves.

Aeroplanes: See Aeroplane.

Aileron: A movable auxiliary surface used to produce a rolling moment about the fore-and-aft axis.

Aircraft: Any form of craft designed for the navigation of the air—aeroplanes, balloons, dirigibles, helicopters, kites, kite balloons, ornithopters, gliders, etc.

Aeroplane: A form of aircraft heavier than air which has wing surfaces for support in the air, with stabilizing surfaces, rudders for steering, and power plant for propulsion through the air. This term is commonly used in a more restricted sense to refer to airplanes fitted with landing gear suited to operation from the land. If the landing gear is suited to operation from the water, the term "seaplane" is used. (See definition.)

Pusher.—A type of aeroplane with the propeller in the rear of the engine.

Tractor.—A type of aeroplane with the propeller in front of the engine.

Air-speed meter: An instrument designed to measure the speed of an aircraft with reference to the air.

Altimeter: An aneroid mounted on an aircraft to indicate continuously its height above the surface of the earth.

Anemometer: Any instrument for measuring the velocity of the wind.

Angle:

Of attack or *of incidence of an aerofoil.*—The acute angle between the direction of the relative wind and the chord of an aerofoil; i. e., the angle between the chord of an aerofoil and its motion relative to the air. (This definition may be extended to any body having an axis.)

Critical.—The angle of attack at which the lift-curve has its first maximum; sometimes referred to as the "burble point." (If the "lift curve" has more than one maximum, this refers to the first one.)

Gliding.—The angle the flight path makes with the horizontal when flying in still air under the influence of gravity alone, i. e., without power from the engine.

Appendix: The hose at the bottom of a balloon used for inflation. In the case of a spherical balloon it also serves for equalization of pressure.

Aspect ratio: The ratio of span to chord of an aerofoil.

Aviator: The operator or pilot of heavier-than-air craft. This term is applied regardless of the sex of the operator.

Axles of an aircraft: Three fixed lines of reference; usually centroidal and mutually rectangular.

The principal longitudinal axis is the plane of symmetry, usually parallel to the axis of the propeller, is called the fore and aft axis (or longitudinal axis); the axis perpendicular to this in the plane of symmetry is called the vertical axis; and the third axis, perpendicular to the other two, is called the transverse axis (or lateral axis). In mathematical discussions the first of these axes, drawn from front to rear, is called the X axis; the second, drawn upward, the Z axis; and the third, forming a "left-handed" system, the Y axis.

Balancing Flaps: See Aileron.

Ballonet: A small balloon within the interior of a balloon or dirigible for the purpose of controlling the ascent or descent, and for maintaining pressure on the outer envelope so as to prevent deformation. The ballonet is kept inflated with air at the required pressure, under the control of a blower and valves.

Balloon: A form of aircraft comprising a gas bag and a basket. The support in the air results from the buoyancy of the air displaced by the gas bag, the form of which is maintained by the pressure of a contained gas lighter than air.

Barrage.—A small spherical captive balloon, raised as a protection against attacks by aeroplanes.

Captice.—A balloon restrained from free flight by means of a cable attaching it to the earth.

Kite.—An elongated form of captive balloon, fitted with tail appendages to keep it headed into the wind, and deriving increased lift due to its axis being inclined to the wind.

Pilot.—A small spherical balloon sent up to show the direction of the wind.

Sounding.—A small spherical balloon sent aloft, without passengers, but with registering meteorological instruments.

Balloon bed: A mooring place on the ground for a captive balloon.

Balloon cloth: The cloth, usually cotton, of which balloon fabrics are made.

Balloon fabric: The finished material, usually rubberized, of which balloon envelopes are made.

Bank: To incline an aeroplane laterally—i. e., to roll it about the fore and aft axis. Right bank is to incline the aeroplane with the right wing down. Also used as a noun to describe the position of an aeroplane when its lateral axis is inclined to the horizontal.

Barograph: An instrument used to record variations in barometric pressure. In aeronautics the charts on which the records are made indicate altitudes directly instead of barometric pressures.

Basket: The car suspended beneath a balloon, for passengers, ballast, etc.

Biplane: A form of aeroplane in which the main supporting surface is divided into two parts, one above the other.

Body of an Aeroplane: The structure which contains the power plant, fuel, passengers, etc.

Bonnet: The appliance, having the form of a parasol, which protects the valve of a spherical balloon against rain.

Bridle: The system of attachment of cable to a balloon, including lines to the suspension band.

Bullseyes: Small rings of wood, metal, etc., forming part of balloon rigging, used for connection or adjustment of ropes.

Burble point: See Angle, critical.

Cabane: A pyramidal framework upon the wing of an airplane, to which stays, etc., are secured.

Camber: The convexity or rise of the curve of an aerofoil from its chord, usually expressed as the ratio of the maximum departure of the curve from the chord to the length of the chord. "Top camber" refers to the top surface of an aerofoil, and "bottom camber" to the bottom surface; "mean camber" is the mean of these two.

Capacity: See Load.

The cubic contents of a balloon.

Center: *Of pressure of an aerofoil.*—The point in the plane of the chords of an aerofoil, prolonged if necessary, through which at any given attitude the line of action of the resultant air force passes. (This definition may be extended to any body.)

Chord:

Of an aerofoil section.—A right line tangent at the front and rear to the under curve of an aerofoil section.

Length.—The length of the chord is the length of the projection of the aerofoil section on the chord.

Clinometer: See Inclinometer.

Concentration ring: A hoop to which are attached the ropes suspending the basket.

Controls: A general term applying to the means provided for operating the devices used to control speed, direction of flight, and attitude of an aircraft.

Control column: The vertical lever by means of which certain of the principal controls are operated, usually those for pitching and rolling.

Crow's foot: A system of diverging short ropes for distributing the pull of a single rope.

Decalage: The angle between the chords of the principal and the tail planes of a monoplane. The same term may be applied to the corresponding angle between the direction of the chord or chords of a biplane and the direction of a tail plane. (This angle is also sometimes known as the longitudinal V of the two planes.)

Dihedral in an aeroplane: The angle included at the intersection of the imaginary surfaces containing the chords of the right and left wings (continued to the plane of symmetry if necessary). This angle is measured in a plane perpendicular to that intersection. The measure of the dihedral is taken as 90° minus one-half of this angle as defined.

The dihedral of the upper wing may and frequently does differ from that of the lower wing in a biplane.

Dirigible: A form of balloon, the outer envelope of which is of elongated form, provided with a propelling system, car, rudders, and stabilizing surfaces.

Nonrigid.—A dirigible whose form is maintained by the pressure of the contained gas assisted by the car-suspension system.

Rigid.—A dirigible whose form is maintained by a rigid structure contained within the envelope.

Semirigid.—A dirigible whose form is maintained by means of a rigid keel and by gas pressure.

Diving rudder: See Elevator.

Dope: A general term applied to the material used in treating the cloth surface of aeroplane members and balloons to increase strength, produce tautness, and act as a filler to maintain air-tightness; it usually has a cellulose base.

Drag: The component parallel to the relative wind of the total force on an aircraft due to the air through which it moves.

That part of the drag due to the wings is called "wing resistance" (formerly called "drift"); that due to the rest of the airplane is called "parasite resistance" (formerly called "head resistance').

Drift: See Drag. Also used as synonymous with "leeway," g. v.

Drift meter: An instrument for the measurement of the angular deviation of an aircraft from a set course, due to cross winds.

Drip cloth: A curtain around the equator of a balloon, which prevents rain from dripping into the basket.

Elevator: A hinged surface for controlling the longitudinal attitude of an aircraft; i. e., its rotation about the transverse axis.

Empannage: See Tail.

Entering edge: The foremost edge of an aerofoil or propeller blade.

Envelope: The portion of the balloon or dirigible which contains the gas.

Equator: The largest horizontal circle of a spherical balloon.

Fins: Small fixed aerofoils attached to different parts of aircraft, in order to promote stability; for example, tail fins, skid fins, etc. Fins are often adjustable. They may be either horizontal or vertical.

Flight path: The path of the center of gravity of an aircraft with reference to the earth.

Float: That portion of the landing gear of an aircraft which provides buoyancy when it is resting on the surface of the water.

Fuselage: See Body.

Gap: The shortest distance between the planes of the chords of the upper and lower wings of a biplane.

Gas bag: See Envelope.

Glide: To fly without engine power.

Glider: A form of aircraft similar to an airplane, but without any power plant.

When utilized in variable winds it makes use of the soaring principles of flight and is sometimes called a soaring machine.

Gore: One of the segments of fabric composing the envelope.

Ground cloth: Canvas placed on the ground to protect a balloon.

Guide rope: The long trailing rope attached to a spherical balloon or dirigible, to serve as a brake and as a variable ballast.

Guy: A rope, chain, wire, or rod attached to an object to guide or steady it, such as guys to wing, tail, or landing gear.

Hangar: A shed for housing balloons or airplanes.

Helicopter: A form of aircraft whose support in the air is derived from the vertical thrust of propellers.

Horn: A short arm fastened to a movable part of an airplane, serving as a lever-arm, e. g., aileron-horn, rudder-horn, elevator-horn.

Inclinometer: An instrument for measuring the angle made by any axis of an aircraft with the horizontal, often called a clinometer.

Inspection window: A small transparent window in the envelope of a balloon or in the wing of an airplane to allow inspection of the interior.

Kite: A form of aircraft without other propelling means than the towline pull, whose support is derived from the force of the wind moving past its surface.

Landing gear: The understructure of an aircraft designed to carry the load when resting on or running on the surface of the land or water.

Leading edge: See Entering edge.

Leeway: The angular deviation from a set course over the earth, due to cross currents of wind, also called drift; hence, "drift meter."

Lift: The component perpendicular to the relative wind, in a vertical plane, of the force on an aerofoil due to the air pressure caused by motion through the air.

Lift bracing: See Stay.

Load:

Dead.—The structure, power plant, and essential accessories of an aircraft.

Full.—The maximum weight which an aircraft can support in flight; the "gross weight."

Useful.—The excess of the full load over the dead-weight of the aircraft itself, i. e., over the weight of its structure, power plant, and essential accessories. (These last must be specified.)

Loading: See Wing, loading.

Lobes: Bags at the stern of an elongated balloon designed to give its directional stability.

Longeron: See Longitudinal.

Longitudinal: A fore-and-aft member of the framing of an airplane body, or of the floats, usually continuous across a number of points of support.

Monoplane: A form of aeroplane whose main supporting surface is a single wing, extending equally on each side of the body.

Mooring band: The band of tape over the top of a balloon to which are attached the mooring ropes.

Nacelle: See Body. Limited to pushers.

Net: A rigging made of ropes and twine on spherical balloons, which supports the entire load carried.

Ornithopter: A form of aircraft deriving its support and propelling force from flapping wings.

Panel: The unit piece of fabric of which the envelope is made.

Parachute: An apparatus, made like an umbrella, used to retard the descent of a falling body.

Patch system: A system of construction in which patches (or adhesive flaps) are used in place of the suspension band.

Permeability: The measure of the loss of gas by diffusion through the intact balloon fabric.

Pitot tube: A tube with an end open square to the fluid stream, used as a detector of an impact pressure. It is usually associated with a coaxial tube surrounding it, having perforations normal to the axis for indicating static pressure; or there is such a tube placed near it and parallel to it, with a closed conical end and having perforations in its side. The velocity of the fluid can be determined from the difference between the impact pressure and the static pressure, as read by a suitable gauge. This instrument is often used to determine the velocity of an aircraft through the air.

Pontoons: See Float.

Pusher: See Aeroplane.

Pylon: A mast or pillar serving as a marker of a course.

Race of a propeller: See Slip stream.

Relative wind: The motion of the air with reference to a moving body. Its direction and velocity, therefore, are found by adding two vectors, one being the velocity of the air with reference to the earth, the other being equal and opposite to the velocity of the body with reference to the earth.

Rip cord: The rope running from the rip panel of a balloon to the basket, the pulling of which causes immediate deflation.

Rip panel: A strip in the upper part of a balloon which is torn off when immediate deflation is desired.

Rudder: A hinged or pivoted surface, usually more or less flat or stream lined, used for the purpose of controlling the attitude of an aircraft about its "vertical" axis, i. e., for controlling its lateral movement.

Rudder bar.—The foot bar by means of which the rudder is operated.

Seaplane: A particular form of airplane in which the landing gear is suited to operation from the water.

Serpent: A short, heavy guide rope.

Side slipping: Sliding downward and inward when making a turn; due to excessive banking. It is the opposite of skidding.

Skidding: Sliding sideways away from the center of the turn in flight. It is usually caused by insufficient banking in a turn, and is the opposite of side slipping.

Skids: Long wooden or metal runners designed to prevent nosing of a land machine when landing or to prevent dropping into holes or ditches in rough ground. Generally designed to function should the landing gear collapse or fail to act.

Slip stream or propeller race: The stream of air driven aft by the propeller and with a velocity relative to the aeroplane greater than that of the surrounding body of still air.

Soaring machine: See Glider.

THE USE OF JIGS, FIXTURES, GAUGES AND TOOLS IN AEROPLANE MANUFACTURE

By R. BORLASE MATTHEWS, WH. EX., A.M.I.C.E., M.I.E.E.E., F.AE.S.

Editorial Introduction

JIGS, tools and gauges, and the machinery with which to make them, are most important factors in the production of aircraft and engines.

The following article, the first of its kind ever published, is the substance of a lecture delivered by the author at the Royal Society of Arts, in London, England. Lieutenant Colonel Sir Henry Fowler, K. B. E., Assistant Director General of Aircraft Production of the British Government, presided. It was followed by expressions of opinions from leading British aircraft manufacturers and military and naval aeronautic engineers.

Introductory

A new industry calls for new methods—*autres jours, autres mœurs*—and the aeroplane industry is therefore not exceptional in demanding many departures from recognized woodworking practice. In the first place the number of machines required today is so large that their construction should be described as a manufacturing rather than a building operation. That is to say, they should preferably be almost entirely put together by the aid of accurate machinery instead of being dependent to such an extent upon the skill of the individual workman, in trying and fitting one part to another until the whole is built up. In this connection it may be remarked that the design of the metal fittings for aeroplanes is not such as to call for any radical departure from previous high class small metal working practice. It is the woodworking side of the business which presents the new scope for initiative. It is this latter aspect, therefore, which will be considered here.

The underlying ideal of the modernized system now advocated, is, that the arrangement of the work and the facilities for economically carrying it out should be planned and designed in the office as distinct from the shops where the actual work is done. For a great number of years it has been realized in engineering establishments that drawings are essential and economical, likewise sooner or later it will be appreciated that drawings of jigs and fixtures are just as necessary.

It may be mentioned in passing, that since the subject is treated as a whole, all the points raised, would obviously not necessarily be applied to the manufacture of one particular type of machine, as so much depends upon circumstances, the size of the order, the probabilities of modifications in design during progress, etc.

Definition of Jigs and Fixtures

The distinction between a jig and a fixture is not an easy one to define, as it is difficult to say where one ends and the other begins. A jig is a device which either holds, or is held on to the work, and at the same time incorporates guides for the various cutting tools; whereas a fixture holds the work while the cutting tools are in operation, but does not contain any special arrangements for guiding the cutting tools. In other words, a fixture is usually a device which must be entirely held or fixed to the machine on which the operation is preformed. The term fixture is often, however, also applied to assembling arrangements of larger size, which form complete units in themselves and are generally permanently attached to concrete foundations. Gauges must, of course, not be confounded with jigs.

A Comparison Between Engine and Aeroplane Manufacture

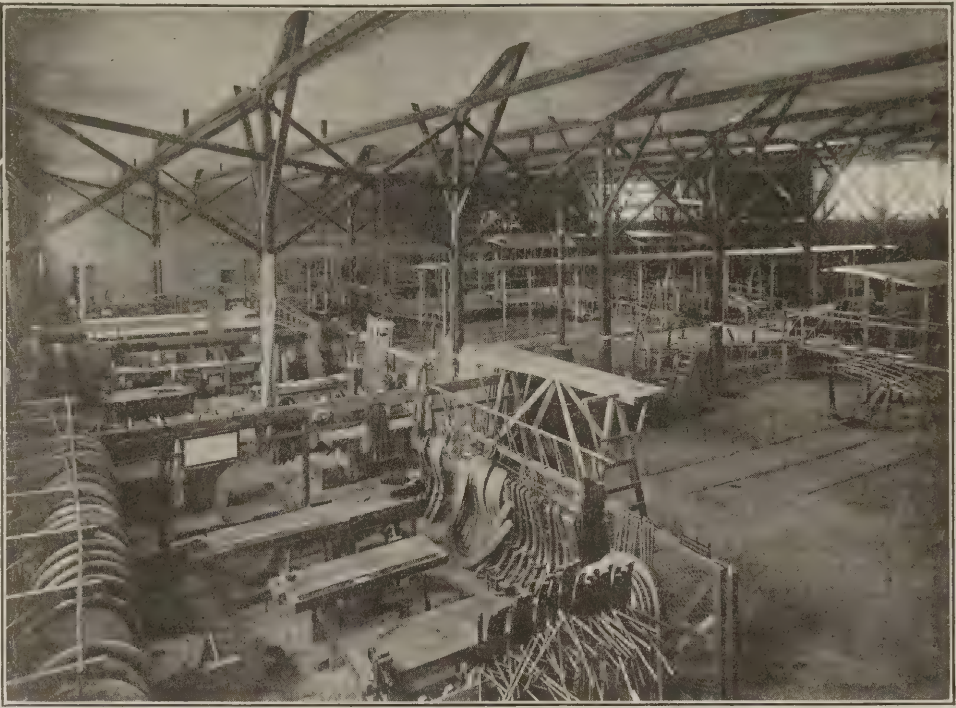
In manufacturing engines in quantities it has long been the practice to use jigs and fixtures in order to speed up production and also to ensure correctness of output. But up to the present, in aeroplane manufacture, this practice has not been adopted to such an extent as it might have been, with the result that it takes very much longer to turn out an aeroplane than is necessary. This delay arises, boh in production of detail parts and also in the assembly of units and complete machines.

Erecting and testing one of the huge Caproni triplanes at the Caproni factory in Italy. In the group on the right, in uniform, is Lieut. Hugo D'Annunzio, in charge of the factory

Considerable time is lost throughout, in trying and fitting the parts into their correct relation, owing to errors in making the details.

For example, assume that in an engine two parts are required to be bolted together. These parts are not clamped together and then drilled both at the same time, nor is one part drilled and the other clamped up to it and drilled through the first. Both parts are drilled separately in jigs. This may be done in a separate department, or even in a separate factory, and still the parts will bolt together in their correct relation.

But in the majority of aeroplane works quite a different state of affairs exists. Take, for example, the case of spars which have to have metal brackets attached to clamp up to other parts. Here the metal parts are placed over the spars when they have been put in position relative to other parts. The spar is then drilled through holes already drilled in the metal parts. This entails much difficulty, because the job is inaccessible; it also promotes inaccuracy, owing to the operator having to drill from both sides to ensure that there will be a clear way for the bolts through both sides. All this troublesome work and subsequent delay would be avoided were the spars and metal parts drilled in jigs. All that would then be necessary would be to push through the bolts and tighten up.



Storage room for dissembled landing chassis at one of the leading Allied aircraft factories. (Official Photo.)

Again, take the spindling of spars. For the sake of compariosn, the milling of straight metal parts may be considered, when the work travels on a horizontal table against the cutter. Here the length to be machined is controlled by stops. In the spindling of spars the job should be placed in a jig having stops upon it, so that it is impossible for the cutter to operate except where it is so desired. By proper design of the jig, the cut out portions will come in correct relation to the overall length and depth.

In cutting form or taper shapes, as, for example, the nose pieces on rotary engines, forming plates are used to compel the tool and the work to move in such a manner that the desired finished form is arrived at. This principle might well be adopted in woodworking, when parts have to be spindled to some special form or taper. The jig would be made with a "former" for bearing against the spindle, which will only allow the cutter to operate in such a way as to produce the desired shape.

The "former" idea should be extended to cover work on the band saw, either for roughing to shape or for finished work when the saw finish is good enough.

For the use of such "forming" jigs on spindling machines, the "former" should bear against a ball bearing embracing the spindle. This will very much reduce the wear on the "former" and so ensure a much longer life for the jig as regards accuracy.

Of course, these "formers" entirely do away with the necessity for marking out shapes, entailing, as the latter operation does, a great amount of time.

The various units that go to make up a complete machine should be assembled in a jig. The jig should hold each unit by at least two locating points. The units, when held in the jig, will all come into their correct relative positions. All that will then have to be done will be to bolt up, through holes drilled in jigs used for making the parts.

Careful consideration as to the cost of production must be given before setting about the design of a jig or fixture, as obviously it is absurd if the cost of the jig is in excess of the anticipated gain. The only exception that would permit of the employment of a jig, which did not comply with the above conditions, is where accuracy of parts is of such importance as to make interchangeability of these parts absolutely essential.

Time and Cost Saved by Use of Jigs

As an illustration of time saving, many aeroplanes could be made in three-fifths of the present time required, if proper jigs and fixtures were in existence. The cost would be reduced by something like twenty-five per cent, this estimate

Preparing Caproni triplane for the mounting of their Fiat, or Isotta-Fraschini motors. (Italian Official Photo.)

being based upon a small number of machines, say 250. On a larger number, say 1,000, the saving in labor would be about fifty per cent, and naturally the saving in labor means increased speed in production.

As a detail example of economy the elevator of a certain machine used to cost in labor alone £2 10s. 0d.; this was immediately reduced to under a sovereign on the introduction of proper jigs. Many other similar cases could be cited.

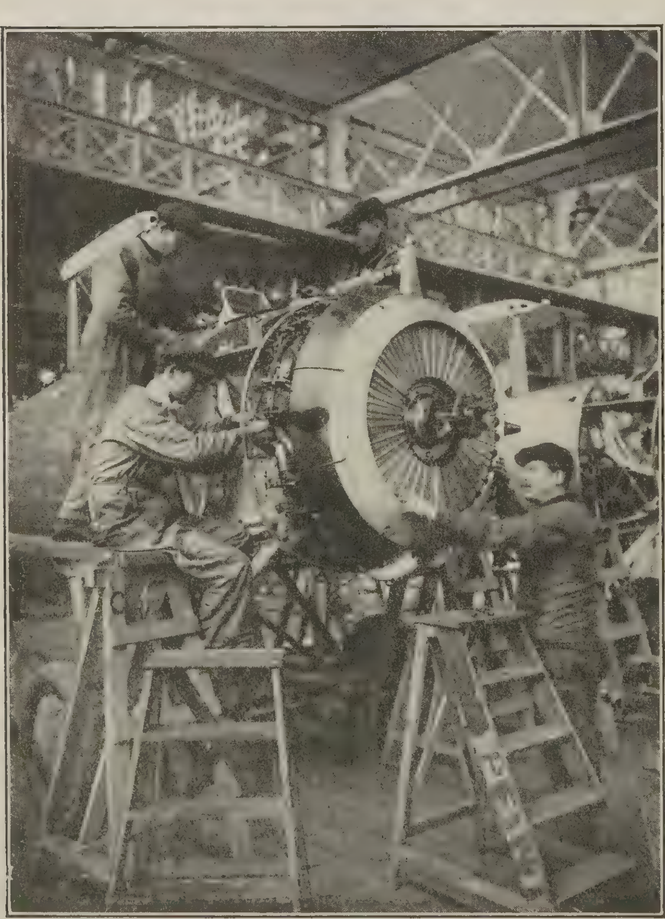
Jig and Fixture Drawings

A modern aeroplane requires at least 1,200 jigs and fixtures. It is obvious that to make so large a number with accuracy, and to ensure that the right number are ordered, these jigs should be made to drawings. At present the comparatively few jigs that are employed are, as a rule, made to the shop foreman's more or less crude ideas. It therefore follows, that when some machine or parts of machines are made by more than one sub-contractor, there will, assuming all sub-contractors work to jigs, be as many different types or styles of jigs to do the same job. Each of these different jigs, to do the same jog, is the result of separate thought.

Here, obviously, is an opportunity for economizing time, for if the jig had been properly designed in a drawing office, all that would have been necessary would have been to have sent a copy of the jig drawing to all sub-contractors, who would then have made their jigs without wasting time in thought and consideration.

The Need of Organized Design

In accordance with well tried principles, sometimes known in the aggregate as Taylorism (out of compliment to the original investigator), it is clear that if work is to be carried out according to scientific laws, the management must be so organized as to execute itself much of the planning formerly left to the initiative of the individual workman. The older method of works management has been described as that of "initiative and incentive," the underlying philosophy of which necessarily leaves the detail solution of daily problems to the man at the bench. The incentive offered in this way, in return for initiative, is merely monetary reward. The method is faulty, because the workman's whole time should be actually taken in doing work with is hands. Even if he had the necessary education and habits of generalization in his thought, he lacks the time and the opportunity for the development of the underlying scientific principles, and without these much effort can be frittered away. Again, any actual development of applications by an individual worker is not easily disseminated amongst others. Under scientific management exact scientific knowledge and methods must earlier or later replace rule-of-thumb ways everywhere. It may be fairly stated that the days have passed when an individual man of strong personality can do big things without the assistance of others. Rather, the present age is one of co-operative specialization, in which all great achievements are accomplished, and will continue to be, by that type of co-operation in which each man performs the function for which he is best suited, preserving fully his own individuality, and losing none of his originality and proper personal initiative. At the same time, however, he must be controlled by and must work harmoniously with his fellow men.



Getting a French Avion-de-chasse ready for its experimental flights. (French Official Photo.)

The Application of Organized Design

The application of scientific principles is naturally just as important in aeroplane manufacture as in any other branch of industry. It has its own special difficulties, but that is all the more reason that steps should be taken to effectively combat them. One of the strongest arguments brought forward against the adoption of a well developed jigging system for aeroplane construction, is that in the present stage of the art, developments are so rapid and so many modifications have to be introduced in the machines that it is impossible to evolve a reasonable system of manufacture. The reply to this is, of course, that the design details of the jigging system must be so elastic as to permit of the introduction of modifications without delaying the progress of work. This only means that all the greater forethought and intelligence must be exercised, and further emphasizes the fact that aeroplane designs must be prepared by practical specialists. From the foregoing remarks it will be gathered that aeroplane jig designs cannot always be as simple as might be desired, since the jigs must be so constructed as to be readily and quickly altered, with a minimum expenditure of time and material, to conform to any required modifications. After all, the general run of modification only affects minor details as a rule, hence the modification bugbear is not so serious a matter as it might appear to be at first encounter, especially as only too many alterations are merely made to facilitate manufacture.

The existence of a jig and fixture drawing office would constitute a most valuable check upon the drawings, and would prevent many of the mistakes which have gone through to the shops in the past. This, in itself, would almost be worth the small extra staff and expense.

It has been estimated that during the life of many aeroplanes something like 400 modifications have to be incorporated, most of which are to correct drawing office errors and to overcome manufacturing troubles. A very considerable portion of these would be eliminated, if jigs and fixtures were designed concurrently with the working drawings of the machines. As regards the elimination of manufacturing difficulties it might be mentioned that one particular aeroplane could be manufactured in one-third the time it now takes, if only the mechanical details were more united to manufacturnig processes.

The obvious moral of the foregoing is that jigs and fixtures should be designed by a drawing office fully conversant with the whole design of the machine, including engine fittings and the fitting of the various instruments. To post all the shops and sub-contractors with this mass of information would obviously take a tremendous lot of time. Therefore it is clear that all the jigs for a machine should be designed by one drawing office and drawings and instructions distributed to the various shops and sub-contractors.

This centralizing of jig design has the great advantage, besides time saved in actual design, that all manufacturers will be posted as to the best way to make machines, having due regard to speed of production and soundness of job.

Another strong reason for a jig designing department is that the smaller aeroplane manufacturers, as a whole, are not mechanical engineers, and have had no experience upon which to fall back in designing jigs. In fact, many of them fail to appreciate that any speeding up of output could be attained by the extended use of jigs. This is due to the fact that in their experience, previous work of a different nature, they did not feel the need of such aids, as their work was more varied.

Classification of Jigs and Fixtures

It has already been mentioned that at least 1,200 jigs and fixtures are necessary for the manufacture of a modern aeroplane. In fact (including jigs for metal fittings) one maker employs 5,000 to great advantage. Hence, it will be of interest to consider the classification of a modern equipment.

1. Parts Jigs

(*a*) *Mill Jigs.*—For sawing, spindling, etc., parts to their exact size.

(*b*) *Drilling Jigs.*—For drilling all the holes called for on the fittings, the necessary bolt holes and the entering holes for large wood screws.

(*c*) *Parts Jigs.*—For completing the small built up parts, ready for attachment to components.

2. Component Jigs

(*a*) *Building Jigs.*—For assembling the various parts into a component (such as ribs, ammunition carriers, etc.)

(*b*) *Taping and Varnishing Jigs.*—For assisting in the quick winding of tape where necessary and for presenting the component in the best possible way for doping and varnishing. These jigs usually take the form of two center points on which the work rotates.

3. Unit Jigs and Fixtures

(*a*) *Unit Assembly Jigs.*—For assembling parts and components into a unit (such as wings, fuselages, ailerons, tail planes, etc.). These should locate the exact position for each part; and the parts, if made correctly, need not be touched by hand, the only work necessary being the insertion of necessary bolts, screws, etc., and wiring.

Girls operating machines used to automatically attach rib reinforcements.
(© Committee on Public Information)

(*b*) *Unit Fixtures.*—Take the form of benches specially made for a certain process, such as covering with fabric, doping, etc., designed to facilitate rapid handling of the unit in construction.

4. Erection Fixtures

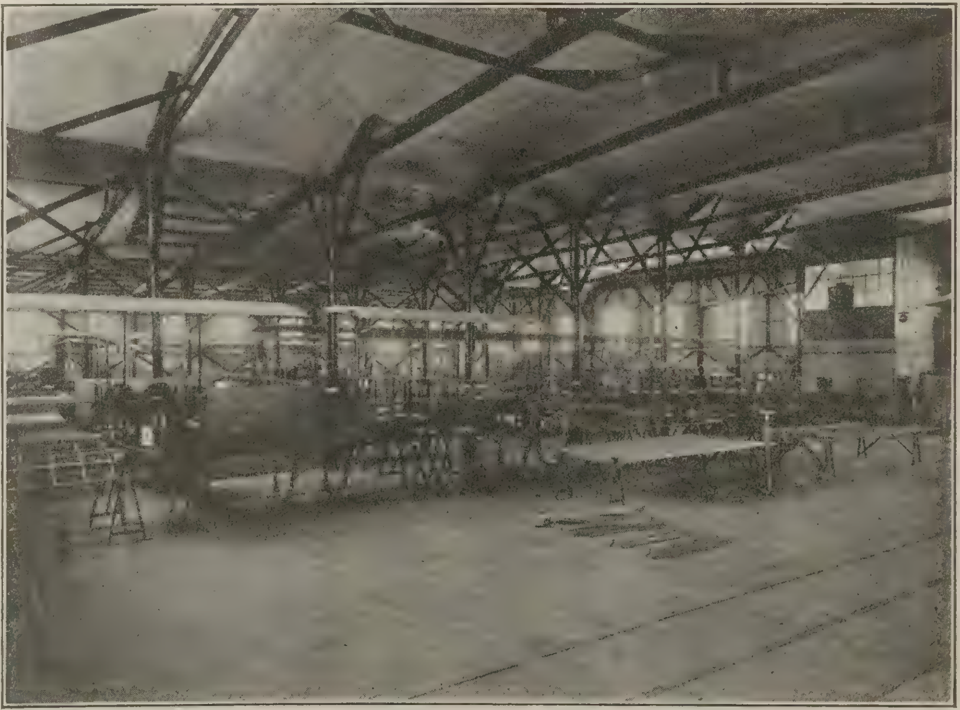
Are constructed to facilitate assembly of the units to the complete machine. A cradle should take the fuselage in its correct position, giving access for affixing the under carriage, the tail skid, and the planes. A supplementary fixture gives the exact position of the wings at the tips and fuselage, and obviates the difficulty of correctly pitching the dihedral, using plumb lines, etc. A tension gauge or tautometer should be used to determine the tautness of wiring, and by careful application a much better rigging will be ensured than is secured by the old method of straining until the correct alignment is secured.

The Principles of Design of Jigs and Fixtures

The general principle that must be followed out in laying out a jig or fixture is to decide upon the locating points of the outline of the clamping or holding arrangements. It should be borne in mind that these latter devices must be as quick acting as possible, and for rough work (*i.e.,* the early operations) some of the locating points will have to be made adjustable. Each jig should be so arranged that the work can only be inserted in the correct way. The ideal method of arranging the clamping and fixing devices is by placing them in the best position to resist the pressure of the cutting tools, that is, all clamps and fixing devices should be integral parts. At the same time complication must be avoided, as one of the objects of a good jig is to eliminate highly skilled labor. Effective support must be provided opposite to surfaces that contain guide bushings. If possible the jig should be so designed that all the locating points are visible to the operator when placing the work in position. Suitable clearance must be provided for the escape of cuttings and chips. Auxiliary devices that facilitate the manipulation of the jig, such as handles, should be provided whenever they assist in shortening the time required.

Many works claim to have very good jig equipments. Unfortunately, however, when the matter is probed into by anyone who really knows the full application of this method of manufacture, the reverse is only too often found to be the case. The usual much-lauded jig equipment generally only comprises a comparatively small number (*i.e.,* in regard to the 1,200 or so previously mentioned as necessary) of so-called board jigs. These consist of flat boards fitted with positioning stops and cam clamps. There is perhaps no more simple and useful all round type of jig than this, and it is very widely used in many most ingenious modifications. Unfortunately, however, it is often incorrectly emloyed, being used as a gauging jig rather than an assembling device. That is to say, a carpenter's bench is placed alongside, and strips of ready planed wood are tried out to length and fitted in place

(*Continued on page* 418)



Jigged up for final alignment before the factory test flights. (French Official Photo.)

The AIRCRAFT TRADE REVIEW

N. E. J.

To Increase Output

The Editor of Aerial Age happens to know at the present moment of several really useful engineers who are on the look-out for responsible positions. One is an exceedingly able motor mechanic, good at handling men, and with considerable experience in aeroplane erection and general handling. Another is a factory organizer with several years' experience. He has had a good technical training, but prefers commercial organization. Any firms who are on the look-out for good men are recommended to write to the Editor on this subject.

Benjamin Williams with Standard

Benjamin L. Williams has resigned as assistant secretary of the Manufacturers' Aircraft Association to accept the position of secretary to the president of the Standard Aircraft Corporation.

Mr. Williams was born at Newton, Sussex Co., N. J., on May 11th, 1880. His start in the business world began in 1892, and his engineering career with the West Orange Water Co. at West Orange, N. J., in 1897, as clerk, being later advanced to assistant superintendent, and in 1904 as superintendent. He qualified for this position by studying the technical side of his work while engaged in the actual construction.

He remained in that position until 1907. In that year he was appointed assistant general superintendent of the Edison companies, Orange, N. J., later became their construction engineer, and was finally made plant engineer. In 1913, Mr. Williams devoted his energies to building management in New York City until the early part of 1917 when the Aircraft Manufacturers' Association was organized and he was made its secretary.

In these several positions, Mr. Williams was an active element in the successful solution of the many problems encountered in the operating of public utility, industrial and isolated building plants, the conditions of which were generally most unfavorable. He is ranked as an expert on industrial plant equipment, maintenance, construction, experimental work and process routing, and has had an excellent experience on water supply and distribution, fire protection, sanitary work, building trades and property valuation. He has made numerous reports on manufacturing and engineering subjects and on matters relating to tax appeals on industrial plants and qualified as an expert on valuation of public utilities in the State of New Jersey.

Mr. Williams' activity in these various classes of engineering work has developed a fund of general business experience that was utilized to excellent advantage by the aircraft manufacturers, and the Standard Aircraft Corp. should find in him a valuable help in co-ordinating its extensive and expanding enterprise.

Fahrig Metal Co.'s New Plant

The Fahrig Metal Co., maker of Fahrig anti-friction metal, which is used for bearings of truck, aeroplane and other high-grade gasoline engines, has opened another plant which will double the production of Fahrig metal, at 34 Commerce Street, New York.

Government Wants Men for Export-Trade Offices

The Government is looking for men capable of taking charge of branch offices of the Bureau of Foreign and Domestic Commerce, Department of Commerce; also men to act as assistants in such offices. These branch offices are located in the principal commercial cities, the salaries ranging from $1,800 to $3,000 for managers, and from $1,200 to $1,800 for assistants.

Applicants should write at once to the Bureau of Foreign and Domestic Commerce, at Washington, as a non-competitive examination will be held on May 16th in various parts of the country. Full details will be furnished upon written application to the Bureau.

Applicants will be examined in export-trade technique, promotion of commerce, and economic geography, and credit will be given for knowledge of foreign languages. The examination will be given under the direction of the Civil Service Commission, but communications should be addressed to the Bureau of Foreign and Domestic Commerce.

The Tractor

The employees of the Standard Aircraft Corporation have published the initial numbers of their house publication, entitled "The Tractor," and from the copies we have received it would seem that the booklet will be a real force in coordinating the social activities and welfare work of this company. It is published monthly.

Acieral Company of America

Acieral Company of America, Office—26 Cortlandt Street, New York, N. Y.; Factory—20 Orange Street, Newark, N. J. Manufacturers of the Acieral metal in ingots, castings, sheets, rods and wires. This metal is an Aluminum composition with a tensile strength of 23,000 pounds per square inch in castings and 60/70,000 pounds in rods and sheets. This company manufactures also manganese bronze of high grade, and is working on large contracts for the Navy on torpedo tubes. Has still capacity for Acieral castings and also rods and sheets. All communications should be addressed to Mr. Alberto de Lavandeyra, secretary of the Acieral Company of America, 26 Cortlandt Street, New York City.

A Simple Process for Refining White Metal Drosses

A new invention that will prove of interest to users of white metals in the Cornwall Process and Dross Converter, for the refining of Tin, Solder, Babbitt, Lead and Type Metal Drosses.

With this process it is possible for manufacturers, large and small, to refine and recover from their metal dross practically all of the metallic contents. What this will mean in economy may be realized by looking over the market quotations of these metals. The cost of operation is claimed by the manufacturers to be less than one-half cent per pound, and the operation is so simple that one man can do all the work. The small space required for its installation is a feature, as twelve feet square is ample.

In these days of scarcity of Tin, the process will enable manufacturers to conserve their supply of pure metal, besides retaining for themselves the profit hitherto made by the refiner in treating the drosses.

The Cornwall Process and Dross Converter is manufactured by Mason, Davis & Co., of Grand Crossing, Chicago, who are also large manufacturers of scales and light grey iron castings.

Woodworking Facilities

The Wangerin-Weickhardt Co., 112-124 Burell St. and 117-121 Austin St., Milwaukee, Wis., a corporation with a working capital of $65,000 and 30,000 feet of floor space, has announced its intention to undertake the manufacture of wood parts for aeroplanes. This firm has a large plant in Milwaukee, Wisconsin, for the building of pipe organs, but, finding a demand for its product greatly curtailed in consequence of the present war-time conditions, decided to utilize a portion of its high-class equipment for the execution of aeroplane woodwork. Considering the fact that no woodworking establishment requires such extremely accurate and precise workmanship as does the building of pipe organs in the construction and assembling of its countless parts, it will readily be understood that the skilled experts employed in that industry are exceptionally qualified for the production of wood parts required in aeroplanes. It may or may not be the program of the aircraft board to standardize the construction of aeroplanes and have them built on a gigantic scale, but any ordinary or extraordinary demand for wood parts to be used in their manufacture can abundantly and skilfully be supplied by some of the large organ building factories. If further particulars are desired address Adolph Wangerin, president of the Wangerin-Weickhardt Co.

General Aeroplane Co. Discontinues Business

Mr. Corwin Van Husan, formerly secretary and treasurer of the General Aeroplane Co., of Detroit, Michigan, has asked Aerial Age to announce that this company has discontinued business on account of his being in the service.

Ford Motor Expanding

Several new contracts have been awarded by the Ford Motor Company of Detroit, for the erection of factories intended for testing of aircraft motors.

Detection of Foreign Oils in Castor Oil Used for Lubricating Aeroplane Motors

The acetyl value is capable of indicating the presence of one to two per cent of foreign olis in castor oil, but the other constants are of little value for the purpose. In the special case of castor oil adulterated with arachis oil the solidification point and the solubility in alcohol are the most sensitive tests (limit, 5 per cent). For smaller amounts of arachis oil the turbidity temperature of the alcoholic solution may be determined. A solution of one volume of pure castor oil in 95 per cent alcohol remains clear when chilled below — 20 degrees C.; but in the presence of arachis oil the solution becomes turbid at temperatures ranging from + 5 degrees or + 6 degrees C. for 5 per cent to — 2 degrees or — 3 degrees C. for 2 per cent of arachis oil. An alcoholic solution of castor oil containing one per cent of arachis oil becomes opalescent at — 4 degrees to — 5 degrees C. and turbid at — 9 degrees C. Foreign oils may be separated from castor oil by shaking 20 c.c. of the sample

Executive heads of the Standard Aircraft Corporation at the testimonial dinner extended to their President, Mr. Harry Bowers Mingle

with 80 c.c. of petroleum spirit of b.pt. 35 degrees to 70 degrees C. in a stoppered graduated cylinder. After settling, the volume of the lower layer containing the castor oil will show an increase of about 11 to 12 c.c. if the oil is pure, or more if foreign oils are present. On evaporating 50 c.c. of the petroleum spirit layer a residue is left, which in the case of 12 samples of pure castor oil ranged from 8.35 to 8.70 per cent of the original oil. Mixtures containing from 30 to one per cent of arachis oil gave residues ranging from 38.61 to 10.04 per cent and by deducting from these the average value for pure castor oil (8.52 per cent), the results agreed closely with theory. The method also effects a concentration of the arachis oil, which facilitates the detection of arachidic acid by Bellier's method. For example, the petroleum spirit extract from castor oil containing 5 per cent of arachis oil will contain 36.7 per cent of that oil—Note in *Jour. Soc. Chem. Ind.* on an article by C. Frabot in *Ann. Chim Analyt.*

Italy Places Hope In Big Battle Planes

Italy is prepared for any exigency on the battlefield now, and if that nation could be supplied with an adequate number of aeroplanes of the Caproni type a decisive victory on the Austrian front would only be a question of a very few months, says Lieutenant Leopold Belloni of the Italian Aviation Corps, sent here as a member of a mission to stimulate the production of these machines.

"The war will be won in the air with aeroplanes," Lieutenant Belloni says. "We want a large number of machines that are capable of inflicting damage upon the enemy's closest assembled forces, supply depots, hangars and factories. We should be able to destroy the enemy's eyes.

"With that end in view we are constructing self-defending battle planes, machines which have several men in the crew, carry four to six machine guns, as well as 1,200 pounds of bombs. With these we hope to penetrate the enemy's line of aerial defence and destroy the nineteen factories that are now working day and night making aeroplanes for the Austrian forces.

"In this way we can surely win. For example, Lieutenant Richthofen, who was killed recently and who was officially credited by the German Government for the destruction of seventy-eight Allies' machines, had to work four years to accomplish the feat. With the machines that we hope to have an entire factory should be demolished in half a day."

Loving cup presented to Mr. Harry Bowers Mingle, president of the Standard Aircraft Corporation, by the employees and executive heads of the corporation

Personal Paragraphs

Harold N. Bliss, formerly production manager, engine department, Thomas-Morse Aircraft Corporation, is now superintendent, engine department.

Sidney W. Colvard, formerly inspection engineer, Curtiss Aeroplane & Motor Corporation, Buffalo, is now assistant general inspector and foreman, Factory E.

Noble Foss of the Sturtevant Aeroplane Co., Jamaica Plain, Mass., is now president and general manager.

George B. Fuller, formerly aeronautical mechanical engineer, Aviation Section, Signal Corps, Dayton, is now assistant chief engineer, Glenn L. Martin Co., Cleveland.

E. K. Hill, formerly in engine department, Thomas-Morse Aircraft Corporation, Ithaca, N.Y., is now in inspection department, Simplex Works. Wright-Martin Aircraft Corporation, New Brunswick, N. J.

Guy A. Little, formerly in dynamometer department, is assistant to chief inspection engineer, Curtiss Aeroplane & Motor Corporation, Buffalo, New York.

E. V. Schaal, formerly in inspection engineering department, is now heat-treatment inspector, Curtiss Aeroplane & Motor Corporation.

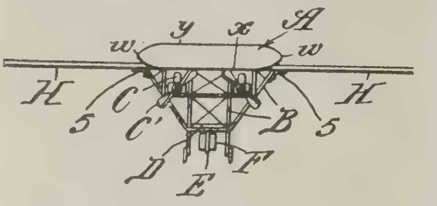
Aero Engineering Squadron at the U. S. School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.

RECENT AERO PATENTS

BY WILLIAM N. MOORE

1,259,804. AERIAL MACHINE. Francis A. Thornton, Richmond Heights, Mo. Filed April 19, 1917. Serial No. 163,206. (Cl. 244—6.)

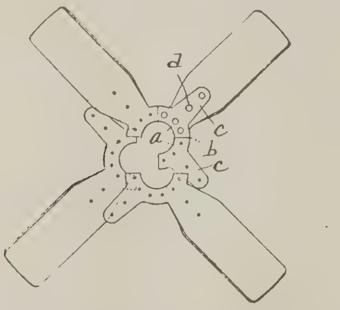
An aerial machine provided with an aerostat of rigid, or substantially rigid, construction whose depth is considerably less than its breadth, a structure of skeleton form depending from said aerostat, motors mounted on said structure adjacent the opposite ends of the aerostat and equipped with propellers, a car for the occupants carried by said structure, and a keel on said structure provided with a shiftable controlling member.



An aerial machine provided with an elongated aerostat having flat under and upper surfaces and ends that are tapered slightly on curved lines, and detachable aeroplane wings projecting laterally in opposite directions from the sides of said aerostat.

1,260,562. FAN CONSTRUCTION. James A. McIntosh, Detroit, Mich., assignor of one-half to John G. Heal, Detroit, Mich. Filed April 7, 1917. Serial No. 160,357. (Cl. 170—173.)

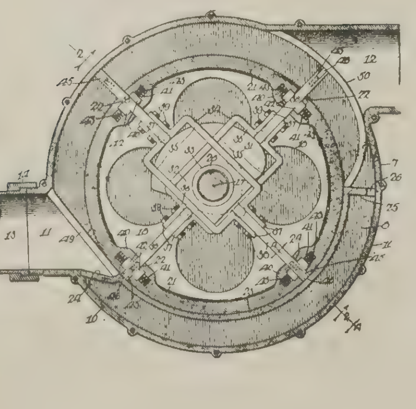
A fan made up of a plurality of blades having continuations in the form of L-shaped half rings and tongues, and means for securing these half rings, tongues and blades in overlapped relation to form a complete fan.



A fan comprising a plurality of blades, each blade having an integral continuation in the form of a segment provided with a projecting tongue, the said projecting tongue adapted to reach to the succeeding blade to which it is secured.

1,259,749. ROTARY ENGINE. Peter Jorgenson, Chicago, Ill. Filed June 6, 1917. Serial No. 173,219. (Cl. 121—75.)

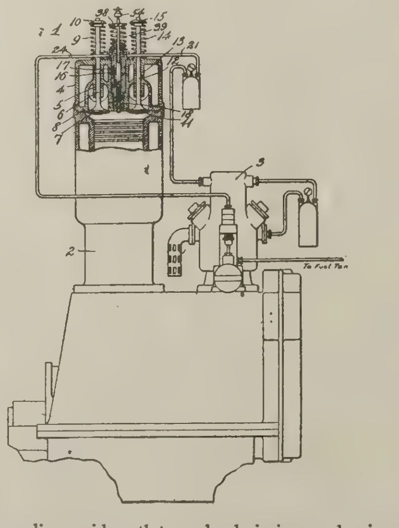
In a rotary engine, the combination with a suitably mounted cylinder having communication with a supply of motive fluid and an exhaust outlet, of a shaft rotatably journaled in the cylinder, a sleeve surrounding said shaft and extended into the cylinder and fixed thereto, a rotor fixed to said shaft and extended therefrom within the cylinder and having a radially slotted peripheral flange, a cam fixed on said sleeve, a collar angular in cross-section and mounted on said sleeve, one or more elongated guide yokes embracingly engaging said collar, rollers on the opposite ends of said yoke or yokes and in contact with the cam, and a wing-piston projected from each end of said yoke or yokes and extended through the radial slots of the flange of the rotor.



In a rotary engine, the combination with a suitably mounted cylinder having communication with a supply of motive fluid and an inlet and exhaust outlet, of a shaft rotatably journaled in the cylinder, a sleeve surrounding said shaft and extended into the cylinder and fixed thereto, a rotor fixed to said shaft and extended therefrom within the cylinder and having a radially slotted peripheral flange located concentrically with respect to the peripheral wall of the cylinder and at a distance thereform, said flange having a recess on each side of each of the slots therein, spring pressed packing-strips located in said recesses, a cam fixed on the aforesaid sleeve, a collar angular in cross-section and mounted on said sleeve, a pair of elongated guide yokes embracingly engaging said collar on each side of the cam and located at right-angles to one another, rollers carried by the opposite ends of each pair of said yokes and in contact with the cam, a wing-piston projected from the outer end of each pair of said yokes and extended through the radial slots of the flange of the rotor and between the spring pressed packing-strips carried thereby, spring actuated packing-strips located in the outer portion of each of said pistons, a segmental partition interposed between the heads of the cylinder and extended from near the inlet opening thereof, to a point near the exhaust opening of the cylinder, and in contact with the flange of the rotor, packing retaining members located in the mouth of the inlet opening and packing retaining members located in the mouth of the exhaust opening and curved inwardly from said opening to the adjacent end of said partition.

1,260,500. MIXING AND ADMISSION VALVE STRUCTURE FOR INTERNAL-COMBUSTION MOTORS. Alexander Winton, Lakewood, Ohio, assignor to The Winton Gas Engine & Manufacturing Company, Cleveland, Ohio, a Corporation of Ohio. Filed June 25, 1914. Serial No. 847,271. (Cl. 123—131.)

A mixing and admission valve for internal combustion motors, comprising a casing having air and fuel inlets and an outlet, a valve seat surrounding said outlet, and admission and mixing valve mechanism arranged therein and comprising a valve stem, a valve mounted upon said stem and coöperating with said seat, and a plurality of rings spaced apart to form annular chambers, alternate rings having external and internal peripheral passages respectively for the gas between said chambers whereby it will pursue a circuitous route through the mechanism and be thoroughly mixed, the rings having the internal peripheral passages being provided with integral spacing lugs near their outer peripheral, and the rings having the external peripheral passages having integral spacing lugs near their inner periphery.

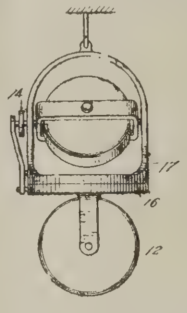


A mixing and admission valve structure for internal combustion motors, comprising a casing having a chamber provided with a valve seat, at its inner end, and a shoulder formed internally above the valve seat, together with a fuel port leading through the casing to a point in said chamber intermediate the shoulder and the outer end of the casing, and an air port leading to the outer end of said chamber, a plurality of spaced rings having openings forming circuitous passages for the mixture, said rings being arranged between said shoulder and fuel inlet opening, a valve coöperating with the valve seat, a stem for said valve extending through said rings and out through the outer end of the casing, a sleeve in said chamber surrounding said stem and engaging the rings and forming an annular peripheral passage for air from the air port to the rings, and clamping means engaging said sleeve for holding said sleeve and rings in place.

A mixing and admission valve structure for internal combustion motors comprising a cylindrical casing having a discharge valve seat at one end, an air inlet, a fuel inlet intermediate of the discharge valve seat and the air inlet, a valve stem extending through said casing, a discharge valve carried thereby and coöperating with said valve seat, a plurality of annular members forming communicating annular mixing pockets between the fuel inlet and the discharge valve, and a sleeve surrounding said stem and coöperating with the inner wall of the casing to restrict the flow of air from the air inlet to the fuel inlet.

1,260,097. GYROSCOPIC COMPASS. Junya Toyokawa, Tokyo, Japan. Original application filed December 21, 1914, Serial No. 878,290. Divided and this application filed May 17, 1917. Serial No. 169,169. (Cl. 74—78.)

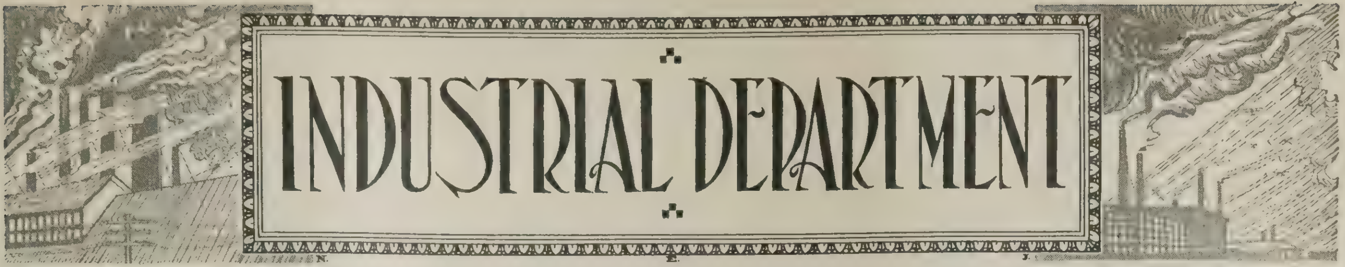
In a gyroscopic compass, gyro wheels respectively having two degree and three degree freedoms of movement, the axes of said wheels, when in equilibrium, always pointing, respectively, to the north-south and to the celestial pole and means to rock the support of one of said wheels relatively to the support of the other wheel.



In a gyroscopic compass, gyro-wheels respectively having two degree and three degree freedoms of movement, the axes of said wheels, when in equilibrium, always pointing, respectively, to the north-south and to the celestial pole, supports for said wheels, and a cam controlled connection between said supports for rocking one of said supports relatively to the other of said supports.

In a gyroscopic compass, gyro-wheels respectively having two degree and three degree freedoms of movement, the axes of said wheels, when in equilibrium, always pointing, respectively, to the north-south and to the celestial pole supports for said wheels, a cam carried by the axle of one of said wheels, and a connection between said cam and the support for the other of said wheels whereby said support is rocked coincidently with the axle of said first mentioned wheel.

In a gyroscopic compass, gyro wheels, respectively having two degree and three degree freedoms of movement, the axes of said wheels, when in equilibrium, always pointing respectively, to the north-south and to the celestial pole, supports for said wheels, a cam carried by the axle of the wheel, the axis of which points to the celestial pole, and means conencting said cam and the support for the wheel the axis of which points to the north-south poles, for rocking said support coincidently with the rotation of the axle of said first mentioned wheel.



INDUSTRIAL DEPARTMENT

GREATER ERIE

Third City of Diversified Interests in the United States

By EDWARD J. CROWELL, Acting Secretary, Erie Board of Commerce

ERIE, Pennsylvania, a city ranking third among the cities of the United States in diversity of its manufactures.

"Made in Erie" is a guarantee of quality, and the proud claim is made that Erie enterprises encircles the earth. From mouse traps, selling for one cent each, to monster electric locomotives, costing what to the majority of men would mean a great fortune, are made in Erie, and Erie manufacturers are always ready to fill orders, guaranteeing quality, service and satisfaction.

Erie is just midway between New York and Chicago and within easy reach of one-half the population of the United States. An Erie business man can enjoy his dinner with his family tonight and tomorrow morning be in New York, Chicago, Philadelphia or Washington as early as any resident of the cities named usually arrives at his office.

Iron ore arriving at immense docks on a superb land locked harbor meets coal and coke from the bituminous fields of Pennsylvania. Therefore, Erie predominates in the iron industry. With modern blast furnaces and up-to-date founders, it is claimed that iron castings are produced in Erie at prices which enable her iron masters to compete with any place on earth.

Always preferring peace with honor, rather than strife, yet when our President declared war, in order that the American ideals of peace, liberty and happiness shall be a perpetual assurance for mankind the world over, Erie's industries, designed for manufacturing articles covering the needs of men in times of peace, promptly became producers of materials for our fighting men, and now, from gas masks to great cannon, over fifty of her great manufacturing plants are turning out war materials in enormous quantities. The same spirit which dominated a hero of the nation and one of Erie's honored sons, alert to his duty when given the order, "Fire when you are ready, Gridley," prevails throughout the city, and great guns are being made that new heroes shall fire them. Already Erie's quota of enlisted men exceeds the number asked for.

When writing of Erie it is a temptation to make mention of its history, which is one of great interest and a record of proud achievement. However, not the *past*, but the *present* and the *future* is thought now in the minds of Erie's progressive citizens. Anyone visiting the city a few years ago and returning today wonders at the progress made and marvels as he hears the enthusiastic believer in the future tell of things done and greater ones which are bound to come to pass.

Phenomenal Growth Now and in Prospect

Throughout the entire city the sound of the pneumatic riveter is heard where great additions are being made to manufacturing plants—additions amounting to millions in cost.

One great company is spending over $2,000,000 for houses for its employes, another over $1,000,000, while yet another has recently purchased several hundred acres of land on which to erect homes. Furthermore, $750,000 is being spent by the United States Government for temporary dormitories for workmen employed in munition plants. Yet, that is not sufficient; so a housing company with a capital of $700,000, all of which was subscribed in ten days, is being organized. This housing company, working under the direct supervision of the United States Government, will begin at once the construction of over one thousand homes. It is promised that the United States Housing Commission will loan said company about $3,500,000 at 4% interest.

Homes built in Erie during the past five years if placed side by side would occupy both sides of twelve miles of city streets and, 840 of them accommodate from two to six families.

Between 12,000 and 15,000 mechanics are now being mustered in various centers and will be sent to Erie as rapidly as they can be accommodated with living quarters.

Erie is growing entirely away from the ideas of yesterday, and things are being done in a day that formerly took months. Even the men right in the thick of it are seeing more accomplished than their most optimistic dreams of a few years ago presented to them.

Erie is located on the south shore of Lake Erie, on Presque Isle Bay, a sheltered body of water which is 4½ miles long and 1½ miles wide, making the finest natural harbor on the chain of great lakes.

Transportation facilities are of the very best, the New York Central, Nickel Plate, Pennsylvania, Erie & Pittsburgh, and Bessemer & Lake Erie railroads passing through or having their termini at Erie.

Three interurban trolley lines connect Erie with all the important cities and territory east, west and south, affording freight as well as passenger service.

A municipally owned water works valued at about $4,000,000 furnishes an abundant supply or pure filtered water for domestic and factory uses at very moderate rates, and manufacturers have a never-failing supply.

The Erie Lighting Company and the Erie County Electric Company have monster power plants, which are supplying Erie industries with power at very low rates, and are sufficiently equipped to supply thousands of horsepower in addition to present demands.

Six large banks, the First National, Second National, Marine National, Erie Trust Company, Securitiy Savings & Trust Company, and the Peoples' Bank, with combined deposits of $26,152,697.44, furnishes ample capital for the needs and expansion of Erie's industries. Bank clearings for 1917 of the six banks were $92,463,103.85, an increase of $21,894,825.67 or 29.1% over 1916. A new bank, the Central Trust & Title Company, with a paid-in capital of $125,000, opened up for business recently. It already has deposits of $250,000, and the combined deposits of all the Erie banks is $26,668,609.94.

Erie is the largest fresh-water fishing port in the world, with an annual haul of from 12,000,000 to 20,000,000 pounds of fish, most of which is handled and shipped by large freezing and packing houses located on Presque Isle Bay.

Erie's location for commercial purposes is unsurpassed. Situated as it is, it is within easy reach of half the population of the United States. Its factories number 326, in 152 of which are employed at the present time 19,324 males and 2,499 females, and it is estimated that in all of the factories and mercantile establishments in the city there are employed 25,000 male and female persons.

The records of the Erie Custom House show that between 2,000 and 3,000 vessels enter and clear from the Erie port each year, and in 1918 there were brought into this port 2,030,484 tons of iron ore and shipped from it 1,312,706 tons of bituminous and anthracite coal, besides the large quantities of grain, lumber, pulp, wood and other merchandise handled.

Erie as a Residence City

Few cities of the United States can be called summer resorts as well as great manufacturing cities.

In speaking of Erie, one can truthfully say that Erie combines both of these wonderful advantages, and this is the reason why Erie is a most delightful place in which to live. The factory worker leaves his place of employment and in less than ten minutes' walk finds himself upon well-paved streets with wide sidewalks, well-kept lawns and beautiful shade trees.

Erie is a city of pretty homes with surroundings so well kept that its residence sections are virtually parks.

Recent careful estimates give Erie a population of 103,000, with 135 miles of streets,—75 miles of which are paved,—fine public buildings, twenty public and nine parochial schools, large public library, modern hotels, two fine hospitals, four theatres, fifteen moving picture houses, one conservatory of music, several large academies of learning, two business colleges, five newspapers, large fraternal homes, churches of every denomination, a $300,000 Y. M. C. A. building, four

FOREIGN NEWS

GREAT BRITAIN

The official statement dealing with aerial operations issued by the War Office on April 22nd says:

"After a long spell of stormy weather, which greatly hampered aerial work, the sky cleared on Sunday and our aeroplanes were able to remain in the air from dawn until dark. Bombing raids were carried out incessantly along the whole front. Over twenty-three tons of bombs were dropped on the Thorout railway station, Menin, Armentieres and various other targets.

"Thousands of rounds of machine gun ammunition were fired by our low-flying machines. Enemy machines were seen in large numbers, but were not aggressive. Eleven German machines were downed in air fighting and six driven down out of control. A hostile observation balloon was also destroyed. Anti-aircraft fire accounted for two other hostile aeroplanes. Five of our machines are missing.

"On Sunday night our night-flying machines again bombed Armentieres, Bapaume, the Chaulnes railway station and Peronne, dropping a total of nine and a half tons of bombs. All the machines returned safely."

"Our bombing machines were very active Monday," says the official statement issued on April 23, on aerial operations. "They dropped nineteen tons of bombs on numerous targets, including the Thorout Railway Station, the Engel ammunition dump and Warneton, Armentieres and Roulers.

"In the air fighting seven machines were brought down, six were driven down out of control or shot down in our lines by anti-aircraft fire and two hostile balloons were destroyed. Three of our machines are missing.

FRANCE

The French official communication of April 22nd reports the following aerial operations:

"On April 20th and 21st four German aeroplanes and two captive balloons were destroyed by our pilots, and a fifth was brought down by our infantry fire. Sixteen enemy machines fell inside their own lines badly damaged after aerial engagements.

"In the same period our bombing aeroplanes carried out numerous sorties. Forty-nine thousand kilos of projectiles were dropped on railway stations, cantonments and enemy aviation grounds in the region of St. Quentin, Jassy, Chaulnes, Roye, Ham, Guiscard and Asfeld. Two fires broke out in the Chaulnes station and the Asfeld station. A munitions depot east of Guiscard was exploded."

On April 25th, the following aerial activity was announced by the French War Office:

"On April 22nd and 23rd seven German aeroplanes and a captive balloon were brought down by our pilots. Ten other machines, badly damaged, fell inside their own lines. It is confirmed that two enemy aeroplanes reported as damaged April 20th were in reality brought down. Five other German machines and a captive balloon likewise were destroyed on April 21, 23 and 24.

"Five thousand kilograms of projectiles were dropped by our bombing 'planes on the railway stations at Nesle, Roye and Chaulnes. Our airoplanes have carried out numerous machine gun attacks on enemy concentrations."

"Allied aeroplanes detected vast, hurried concentrations of German troops yesterday," says an Associated Press dispatch dated April 24th, "enabling the Allies to prepare the stiffest resistance when the third German push was launched this morning."

According to the announcement of operations on the Balkan front, dated April 21st:

"An enemy machine was brought down by a British aviator northeast of Petritch."

During February, French naval aviation forces carried out more than 2,100 flights. Patrols and reconnaissances by airships amounted to about 200, and by captive balloons to 100. On several occasions mines were discovered or submarines successfully attacked.

A German aeroplane which was approaching Paris on the night of April 23rd was caught by the French searchlights, taken under a violent fire and compelled to land near Nogent l'Artaud. It was a bombarding triplane.

The crew, consisting of a lieutenant, a non-commissioned officer and a machine-gunner, was captured.

An official statement told of the attempted raid, as follows:

"Suspicious sounds of aeroplane engines having been reported by watching posts as coming in the direction of Paris, warning was given at 11:36 P. M. No aeroplane crossed the fire curtain or flew over the Paris district. All clear was sounded at 1:02 P. M."

GERMANY

"During the last two days thirty enemy aeroplanes were brought down," says the German official announcement of April 23d.

GREAT BRITAIN

The official statement relative to air operations issued by the War Office on April 24th reads:

"The weather on Tuesday was unfavorable for flying until 5 P. M., after which sharp fighting occurred in the air. Reconnaissances were carried out at a low altitude throughout the day. Merville, Estaires, Steenwerck, La Gorgue, the Chaulnes railway junction and the docks at Ostend were heavily bombed.

"Fourteen hostile machines were brought down, two were driven down out of control and one as shot down back of our lines by anti-aircraft fire. One of our machines is missing.

"During the night twenty-one tons of bombs were dropped on different targets, including Roulers, Merville, Armentieres, Baupaume, the railway stations at Chaulnes, Thorout, Tournai and Courtrai and the docks at Zeebrugge. Direct hits were obtained on all these targets, and several fires were started. All our machines returned.

The Admiralty has issued the following on April 24th:

"In to-day's German wireless the following statement appears: 'From papers found on American aviators who were shot down it has been proved that for their own safety many of them crossed over on hospital ships, certified as members of the American Ambulance Service in France.'

"The Secretary of the Admiralty makes the following statement: 'No hospital ship, British or American, has ever carried anybody but invalids and the necessary medical staff. Further, there are no hospital ships working on the 'cross-Channel route. The whole statement, therefore, is a fabrication. The American naval authorities state that they have some few aviators who were in the Allied ambulance service in France before the United States came into the war, but even in such cases these men crossed the Atlantic in ordinary ships, taking their full chance of being torpedoed.' "

An official statement issued April 27th on aerial operations says:

"Except for low reconnoissances on the battlefront Friday little flying was possible owing to the thick mist.

"Two low flying German aeroplanes were brought down by our infantry. None of our machines are missing."

The Air Ministry announced on April 27th, that the number of bombs dropped by the British over enemy lines in France opposite the British front during March, was 23,099 by day, and 13,080 by night. The enemy dropped in the area occupied by British troops 517 by day and 1,948 by night.

Despite reports from Berlin to the contrary, great damage was done on April 23rd by the British in their raid against Zeebrugge and Ostend. The accounts of some of those who were in the action show that it was one of the most gallant episodes of the war. An official bulletin issued on April 24th by the British Admiralty says:

"Following the naval operation on the enemy's coast yesteday morning, observations were made by aircraft and bomb attacks carried out. Observation was difficult owing to the clouds, and on this account our machines descended as low as fifty feet.

"A clear break twenty yards wide was observed in the Zeebrugge Mole at its inner end. At Ostend a sunken object was seen lying between the piers and blocking the greater part of the fairway.

"Numerous bombs were dropped on objectives on shore."

The Order of Knight Commander of the Bath has been conferred on Admiral Keyes in recognition of his services in command of the operations against Zeebrugge and Ostend. Commander Carpenter for his services in command of the Vindictive has been promoted.

A British airman bombed Zeebrugge mole while the kaiser was inspecting the results of the recent naval raid there, according to news from Copenhagen.

The kaiser remained on the mole and completed his inspection.

Vice-Admiral Schroeder, the commander at Zeebrugge, according to reports reaching here, will be deprived of his command for being taken by surprise by the British.

In urging the British nation to an increased output of aeroplanes "The Daily Mail," in an editorial, dwells on the importance for Germany of Russia's defection as affecting supremacy in the air. Russian aeroplanes, it says, had great reputation in Germany, and some of them had been used as models by German manufacturers, according to Associated Press correspondence.

"The collapse of Russia," it adds, "enables Germany to exploit and turn to its own use all factories and aerodromes in Russia, and as many more as Russian labor, now looking around hungrily for a job, can be induced to construct. Factories for the manufacture of certain types of machinees are springing up from Petrograd to Moscow, not to mention those already in existence which are, or soon will be, German."

"The Daily Mail" specifies eight existing establishments, including the Korpusnoi aerodrome in Petrograd, the largest in Europe.

Photographs can be taken at the rate of one a second with the new multiple aeroplane camera used by the Allied airmen, according to "The Daily Express," of London. In this way it is possible to map the German lines with marvellous precision.

One multiple camera alone is capable of 750 exposures with a single loading. The secret of this great capacity lies in its use of ordinary motion-picture film, the turning of the film for a new exposure being accomplished automatically.

ITALY

The Italian official announcement for **April 26th states that two aeroplanes were destroyed by Italian aviators.**

The Italian official announcement for December 26th states that two aeroplanes were destroyed by Italian aviators.

Italian seaplanes made a reconnaissance over the Austrian naval base at Pola and also over Rovigno, bombing destroyers and merchantmen, said a press dispatch from Rome, dated April 26th.

Two bombs struck an Austrian destroyer—a large Austrian warship in the Fassave Canal, and several merchantmen were also shelled. One Austrian seaplane was brought down.

One of the Italian seaplanes was compelled to alight on a choppy sea. A daring rescue was made by an Italian pilot from another machine who swooped down, rescuing the pilot of the disabled aircraft.

The Italians got back to their bases although heavily shelled.

The raid was made on April 22nd.

Important Announcement to Model News Readers

AERIAL AGE is fortunate in having secured the services of Mr. John F. McMahon as its Model News Editor. Beginning with the next issue, Mr. McMahon will take charge of this department, and with the cooperation of the model clubs and individual model fliers throughout the country, will further the interests of this important and instructive branch of aeronautics.

Mr. McMahon is well known to model builders in the vicinity of this city, as his connection with model flying dates back to about 1910, when the sport did not receive the support and interest it does now. One of McMahon's models was the first to fly over 2,000 feet, and he has participated in and won numerous model and glider competitions. Many fliers will remember the success of his experiments with compressed air engines and compressed air driven models.

In 1912 McMahon was Scretary of the Long Island Model Aero Club, and he has been closely associated with model activities since that time. The secretaries of all Model Clubs are requested to correspond with our Model Editor, who will arrange to publish reports and club notices from time to time.

Photographs and descriptions of models for publication on the Model News page are especially desirable, and their receipt will be prompt acknowledged. Young men who were model fliers, and now engaged in various branches of the United States air forces, are asked to write telling how their model experience has assisted them in becoming acquainted with the work they are doing to make America supreme in the air.

(Address all communications to: John F. McMahon, Model Editor, Aerial Age Weekly, 280 Madison Avenue, New York City.)

Mr. John F. McMahon, who is now Model Editor of Aerial Age Weekly

The Future of the Mechanical Driven Model

By Edwin A. Jenkins

Aeromodellists throughout the world almost unanimously agree that the rubber-strand driven model will be succeeded by the mechanical driven machine. The disadvantages of a rubber strand motor are numerous. At its best, such a motor has a very short life.

There are four main kinds of mechanical motors for models, namely, compressed air, steam, electric, and spring motors. The last two mentioned are out of the question, because of their excessive weight and numerous mechanical difficulties. There remains only the compressed air and steam motors. English model flyers are partial to the steam motor, while Americans favor the compressed air motor. The chief fault of the steam motor lies in its complicatedness and its difficulty to run. There remains only the compressed air model motor. Of these motors, the best are the three and five cylinder rotary types, because these types, being rotary, do not have so much vibration as the stationary types. Thus far the compressed air motor is far from perfect, but with the show of a little ingenuity there is no reason why this type of motor should not eclipse all others in the field.

Early Model Experiments

By F. J. Camm

Although the model aeroplane represents in miniature the embodiment of the same basic laws as those which apply to the full-size machine, yet so simple has its manipulation become (partly owing to the standardization which has taken place in flying models, *i.e.*, those not possessing a full-size prototype) that few of those who fly the model aeroplane ever appreciate the vast amount of endeavor which has conduced to the comparative simplicity with which it is now possible to fly them. That endeavor represents the work of the pioneers —men who, devoted their life to the problem of artificial flight, sacrificing their money with no thought of tangible reward save what success might germinate from their work. They knew, these tyros, that a gulf of probably two or three centuries separated them from the consummation of their hopes. Each only hoped that when, perchance, senility terminated his efforts, one term at least might be eliminated from the equation, and the solution brought so much nearer.

And yet they had a reward—the reward meted out to most pioneers in all branches of science: termed "cranks," classed with seekers of perpetual motion, and (the inevitable conclusion of the sequence) their work appreciated at its true value, and their name revered long after their obituary had been written.

The results obtained by many of these experimenters are scattered through a great number of tomes, musty with age, which now repose, surrounded with a halo of academic interest, in the libraries and archives of divers societies and institutes connected with the science of aeronautics.

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Why He Was Apprehensive

Sandy McTavish was a skilled worker in an aircraft factory. After hesitation he agreed to make a flight with the star tester. During the flight the aviator asked how he was enjoying it.

"To tell the truth," said Sandy, "I would rather be on the ground."

"Tut tut, I'm just thinking of looping the loop."

"For Heaven's sake, don't do that!" yelled the now very nervous Sandy, "I've some silver in my vest pocket!"

Exposing His Ignorance

Landsman: "What's the horse-power of that engine you're running?"

Jackie: "It's got no horse-power. Can't you see its a donkey engine?"

Essential

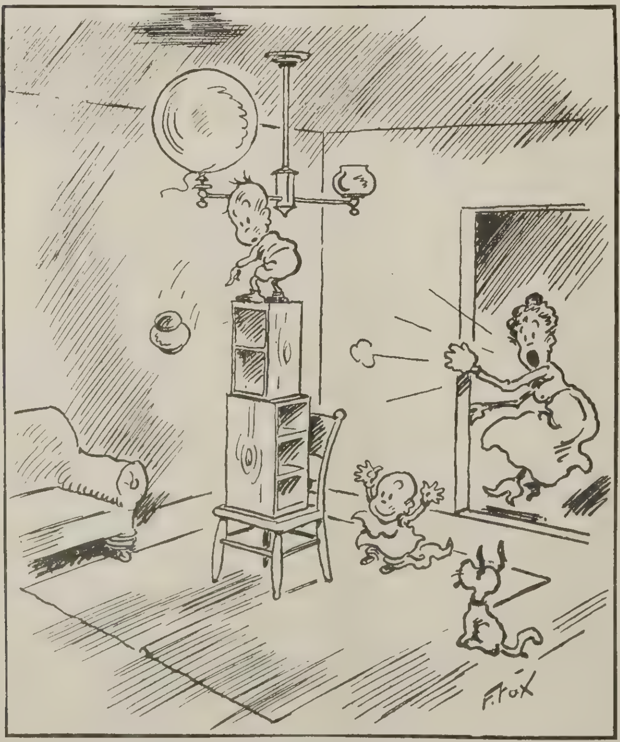
The novice was not enjoying his first trip through the air, and his more experienced companion regarded him in some amusement.

"I say, Bill, what's on your mind?" he demanded.

"I was just thinking about Abraham Lincoln," replied Bill, thoughtfully.

"Abraham Lincoln?"

"Yes, I was thinking how truthful he spoke when he said a man's legs ought to be just long enough to reach the ground."



Little Egbert's best stunt this week was an almost successful attempt to get his balloon filled with real gas.—F. Fox, in the N. Y. Evening Sun.

The Maiden Trip

The captain puffed at a bulldog pipe
  And a gleam was in his eye;
For he feared no foe in the earth below
  Or up in the azure sky.
The day was fine, and the hour was noon,
When we both set off in a kite balloon.

'Twas a maiden flight in that respect,
  But we didn't care a rap;
For we'd wandered wide in a Martinsyde,
  And figured in many a scrap.
A kite balloon was a school-kid's toy,
A pastime planned for an infant boy!

We took a luncheon basket up,
  And we had it stocked right well
With a leg of ham, and some buns and jam,
  And a sparkling Muscatel.
For we meant to do the thing in style,
And to make the merry game worth while!

But when we had soared three thousand feet
  We weren't in the mood for mirth;
For the car it rocked till be both were crocked,
  And felt like nought on earth.
"Oh, nevermore!" the captain cried,
As he lovingly lurched towards the side!

For over an hour we hovered there
  Like criminals on the rack;
We bumped and swayed like a drunk parade,
  Or a squad of men on "pack."
We murmured a deadly Hymn of Hate
And bitterly strafed at our sorry fate!

We descended then, with pallid cheeks,
  And with doleful, downcast eyes;
And we felt no more like dogs of war
  And conquerors of the skies.
May our next exciting flight be soon,
But not—oh, not in a kite balloon!

G. R. S.

The Aviator's Philosophy

Of two things, one thing is certain. Either you're in the air or you're on the ground.

If you're on the ground there is no need to worry. If you're in the air, one of two things is certain. Either you're flying straight or you're turning over.

If you're flying straight there is no need to worry. If you are turning over, one of two things is certain. Either you fall or you don't.

If you don't fall, there is no need to worry. If you do fall, one of two things is certain. Either you're injured or you're not injured.

If you're not injured, there is no need to worry. If you're injured, one of two things is certain. Either you're injured slightly or you're injured seriously.

If you're injured slightly, there is no need to worry. If you're injured seriously, one of two things is certain. Either you recover or you die.

If you recover, there is no need to worry. If you die, you can't worry.—From *The Aileron,* the organ of No. 1 Training Depôt Station, R.F.C.)

Gillette Safety Razor

Have You Seen the New Gillette Specially Designed for the Fighting Man?

THESE models were designed by members of the Gillette Organization who have seen service with the Colors and know what the soldier is up against.

Hundreds of officers and men are buying them — the U. S. Service Set in metal case, and the new Khaki-covered sets for Uncle Sam's soldiers and officers.

The Gillette is the one razor for the man who is doing things — the one razor with world-wide use and reputation.

When a man wants new Blades he can get them at any Post Exchange or Y. M. C. A. Hut — here in America or Overseas.

Our Paris Office carries stocks — is constantly supplying the American Expeditionary Forces. Gillette Safety Razors and Blades on sale everywhere in France, England, Italy and the Eastern battle fronts.

The Name "Gillette" Means the Same Thing to Every Fighting Man

THE severest test of the usefulness of anything is—will it fit the soldier's need.

The fighting men of the Allied Armies and Navies use more Gillettes than of all other makes of razors put together.

They have proved the quality of the Gillette shave—with even the most tender skin and the most stubby beard.

There isn't a shaving condition anywhere on earth that the Gillette hasn't solved—No Stropping, No Honing—blades always sharp, always ready.

If you have a boy or a boy friend in the Service, or likely to be called to the Colors give him a Gillette—complete, compact, no strops or hones to clutter up the kit.

building and loan associations, two public markets, nine parks within the city limits, two summer resorts,—Waldemeer and Four Mile Creek,—with bathing facilities as fine as can be had at the seashore resorts.

The Pennsylvania Gas Company furnishes the city with natural gas for fuel and lighting purposes at 37 cents per thousand cubic feet. This gas is piped direct to Erie from the adjacent gas fields of Pennsylvania and has been the chief source of fuel supply for our citizens since 1885.

The assessed valuation of real estate within the city limits on January 1, 1918, was $56,839,892 (actual valuation estimated at over $75,000,000). This does not include exempted real estate with an estimated valuation of $4,406,754.

Erie has commission form of government, municipal control being vested in a mayor and four members of council.

The school property, with a valuation of $2,500,000, is managed by a school board consisting of nine members elected at large. A vocational High School, said to be the finest in Pennsylvania, is now being erected at a cost of $700,000, and adjoining it there will be a stadium with a capacity for seating 12,000 persons.

The city's fire-fighting facilities are among the best in the country, having a full paid department of 107 men and modern equipment.

The city maintains its own garbage incinerating plant and collection system and operates its own asphalt repair plant.

Erie has no slums and its many charitable institutions take good care of its sick and unfortunate.

Among the municipal improvement activities under way, contracts have been made between the city and the New York Central and Pennsylvania railroads for the building of six subways and a new union depot at a cost of about $2,000,000, the entire building program to be completed by May 1, 1921. The work of covering Mill Creek and Garrison Run, the building of a sewage disposal plant, the erection of yet another High School, and other large grade school buildings; also many miles of new pavements contracted for means that several millions of dollars more have been provided that Erie shall be even a better place to reside than now.

Opportunities Which Erie Offers

After a careful survey of the diversified industries of our rapidly growing city, it is believed there might be established within the city of Erie, with profit to those who have the capital and know their business lines thoroughly, factories which will manufacture automobiles, cutlery, aeroplanes, rolling mill products, boiler plates, boiler tubes, ships, furniture, agricultural implements, paving brick, knitted goods, hosiery, clothing and shoes. Erie's land locked harbor offers a particularly desirable location for the establishment of ship yards and plants for the buildings of aeroplanes and hydroplanes.

AKRON—THE CITY OF OPPORTUNITY

By VINCENT S. STEVENS

Secretary, Akron Chamber of Commerce

AKRON, Ohio, the foremost city in the world in the manufacture of rubber tires and other rubber products, has gained an added distinction in becoming the city upon which the war department of the United States depends mainly for the construction of lighter-than-air craft.

A large number of dirigibles, spherical balloons and captive kite balloons are being built by the Goodyear Tire & Rubber Co. and the B. F. Goodrich Co.

The balloons are assembled and tested at the Goodyear Tire balloon field at Wingfoot Lake, a short distance from Akron. A dirigible balloon training school is operated at the field for the government, and eighty marines are now being instructed to become pilots. Nearly every day one or more spherical balloon flights are made from the field and a dozen or more dirigible flights.

Akron's place in the field of lighter-than-air craft manufacture is largely due to the experiments made by the Goodyear Tire & Rubber Co. in the early days of the industry, when practically all balloons were made of varnished fabrics. Believing that balloons made from rubberized fabrics would be greatly superior, experiments were made which finally resulted in a perfect product.

In 1911 the famous "Goodyear" balloon was built, a spherical racing balloon of 80,000 cubic feet capacity. The "Goodyear" won the national race in this country in 1913 and again in 1914. It also won the International Race for the James Gordon Bennett cup out of Paris, October 12, 1913. In this race the balloon traveled 550 miles, crossing the English Channel and landing in England after being in the air 43 hours.

At the time of the entrance of the United States into the war, the Goodyear Tire & Rubber Co. was the only company in the country equipped to manufacture balloons constructed from rubberized fabric. It was in a position to immediately begin filling orders for the government. The B. F. Goodrich Co. soon entered the field and is now turning out various types of balloons under government orders. These were first assembled and tested at Chicago, but later, to save time, arrangements were made to have this done at the Goodyear field.

Besides lighter-than-air craft, Akron industries are actively engaged in the manufacture of aeroplane tires and other accessories of aeroplanes in which rubber is a part of the composition. In addition to the Goodyear Tire & Rubber Co. and the B. F. Goodrich Co., the Firestone Tire & Rubber Co. and the Miller Rubber Co. are working on large orders.

The rubber industry was started in Akron in 1869, and it has grown until now there are twenty-four rubber companies in this city, with an aggregate capitalization of about $175,000,000, and they employ about 51,000 persons in the manufacture of many thousand different kinds of articles in which rubber is used.

Honor the Brave

Blood is mantling in the face,
Indignation fills the heart
At thought our great and noble race
Should fail to do its obvious part,
To those who venture in the air,
Who freely risk their limbs and lives,
Who glory in the very dare
To save our homes, our babes, our wives.

On "matador" of cruel Spain
A golden shower falls each day
For slight risk run in giving pain
To poor, dumb brutes when brought to bay.
The force that makes all nations grand
Is stimulation of the brave,
Appreciation of the stand
Their heroes take on land and wave.

And shall our eagles of the skies,
Who rush our country to defend
Be forced to deem their sacrifice
Is but a useless way to end?
Oh shame upon Ameria
That she should cut the "living wage"
Of men who venture near and far
Protecting her from Hunnish rage.

Then wipe the stain from off our shield
With gen'rous hand the brave reward,
And send them out in air or field
With well-filled purse and finest sword.

George L. Upshur.

Berckmans Scout Camouflaged

This is the first American-built camouflaged airplane. It is equipped with 100 h.p. revolving engine and can climb higher than the Woolworth Building and also return to earth in a single minute. It is Valsparred.

Airplanes Camouflaged with Valspar's Aid—

The new system of camouflaging used on this Berckmans Scout was invented by W. A. Mackay, an American, and Valspar (also American) is an important factor in its success.

To insure absolute permanence under varying conditions of service the non-fading monochromatic colors which produce the camouflage *are ground in Valspar.*

The marvelous durability of Valspar, under all the superstrenuous trials of active war-service, has given it the supreme position as the varnish for both airplanes and seaplanes in the Allied service.

Valspar is used by the American and Allied governments because it is not only water-proof but resists the action of gasoline, oils, and greases, and is immune from weather conditions.

Valentine Products used by the world's leading airplane-makers include: Valspar Varnish, Valspar Bristol Enamel, Valspar Olive-Drab Enamel, Valspar Low Visibility Gray Enamel; Valspar Black Enamel, Valspar Filler (Wood), Valspar Primer (Metal), Valspar Primer (Wood), Valspar Khaki Enamel, Valspar Aluminum Paint. Dipping, Spraying and Brushing coatings of all kinds, Quick-Drying Insignia Colors.

(*Continued from page* 392)

1½ inches deep at the ends, curving thence to a point in the center, where the depth shall be 3 inches; the two lower pockets are to be cut bellows style, 9 inches deep, 8½ inches wide at the to pand 9½ inches wide at the bottom, inside measurements, the piece to form the bellows is to be 2½ inches wide, inside measurement, one edge to be seamed and stitched to the pocket, the other to be turned in and neatly stitched to the coat, the corners to be mitered so as to make the pocket lies close to the coat, the lower edges of the pocket and bellows piece to be rounded, these pockets to be sewed close to the bottom of the coat. There shall be a flap of two-ply cloth stitched 1 inch above each lower pocket opening 3½ inches wide at the point in the center and curving to 1½ inches wide at each side; there shall be a button hole worked vertically in the point of the flap, the flap to be stitched to the coat on a horizontal line with the bottom button. Extending from the neck at the front of the coat on each side to the top of each upper pocket there shall be two welted gore seams about 1½ inches apart at the collar and 2 inches apart at the top of the pocket. Inside pockets may be added if desired. Material to be of forestry green as prescribed in Uniform Regulations, U. S. Marine Corps, for winter field service.

Note.—Officers or student officers will not be required to have coats in their possession altered to conform to the foregoing changes.

Breeches.—To be of same pattern as winter field breeches, Uniform Regulations, U. S. Marine Corps. Material to be of forestry green.

Trousers.—To be of same pattern as undress trousers, Uniform Regulations, U. S. Navy. Material to be of forestry green. To be worn when leggings are not worn.

Overcoat.—To be of same pattern as the Uniform Overcoat Regulations, U. S. Navy. Material will be of forestry green. Shall be knee length and shall have five plain, brown buttons, 1½ inches in diameter, on each front. Lower buttons placed about three inches below the sword belt, the others equally spaced up to the throat. Sleeve stripes shall be brown.

Gloves.—Brown.

Caps.—Similar to service blue caps, Uniform Regulations, U. S. Navy, except that top will be of forestry green material.

Shoes.—High laced shoes of tan leather.

Leggings.—To be of tan leather and of the pattern known as "puttee."

Flannel shirts.—Similar to flannel shirts, Marine Corps Regulations.

Shoulder marks.—As per Uniform Regulations, U. S. Navy, except that shoulder marks to be worn on coat shall be sewn on and shall be worked over hair cloth or similar stiffening material. Shoulder marks on overcoat will be worn as on blue service overcoat.

Buttons.—As per Uniform Regulations, U. S. Navy.

SUMMER FLIGHT SERVICE

To be the same as winter flight service except that material shall be lighter in weight.

RAINCLOTHES

Raincoat.—To be of rubber cloth or waterproof material; of the same pattern and color as the winter flight service overcoat except that the bottom shall reach to within 12 inches of the ground, and the middle point of the opening of the pockets shall be level with the elbow. There shall also be a slash vent open through the coat at the opening of the pocket. Sleeve stripes shall be worn, but shoulder marks will be omitted.

Rainproof cap cover.—To be of waterproof material; the color to be approximately the same as the flight service uniform.

WORKING DRESS

To be a one-piece overall suit, capable of being worn over uniform and to be made of canvas, khaki or moleskin.

Naval aviator's device.—Device for naval aviators will be a winged foul anchor to be worn by qualified naval aviators. This device will be issued by the Bureau of Navigation to officers and men of the Navy and Marine Corps, who qualify as naval aviators, and will be worn on the left breast.

Summer and winter flight uniforms only will be required of officers of the Naval Reserve Flying Corps, but they may provide themselves with Navy service uniform as prescribed for Naval Reserve officers, if they so desire, to be worn when not on duty specified below. Summer or winter flight uniforms will be worn by all officers on aviation duty attached to naval air stations and naval aviation detachments, ashore, and may be worn on duty in connection with inspection or tests of aircraft and their material, and on such other occasions as may be prescribed by competent authority.

STUDENT OFFICERS

Caps.—To be the same as for commissioned officers, except that chin straps will be ¼ inch in width, and the device will be the same as that worn by midshipmen. This cap device is a gold foul anchor in a vertical position, total length 1¾ inches, width 1⅛ inches.

Shoulder marks.—Will not be worn.

Leggings.—Student officers will wear the wrap leggings instead of the leather puttees.

Approved April 1, 1918.

JOSEPHUS DANIELS,
Secretary of the Navy.

(*Continued from page* 395)

Span or spread: The maximum distance laterally from tip to tip of an airplane wing, or the lateral dimension of an aerofoil.

Stability: A quality in virtue of which an airplane in flight tends to return to its previous attitude after a slight disturbance.

- *Directional*.—Stability with reference to the vertical axis.
- *Dynamical*.—The quality of an aircraft in flight which causes it to return to a condition of equilibrium after its attitude has been changed by meeting some disturbance, e. g., a gust. This return to equilibrium is due to two factors; first, the inherent righting moments of the structure; second, the damping of the oscillations by the tail, etc.
- *Inherent*.—Stability of an aircraft due to the disposition and arrangement of its fixed parts—i. e., that property which causes it to return to its normal attitude of flight without the use of the controls.
- *Lateral*.—Stability with reference to the longitudinal (or fore and aft) axis.
- *Longitudinal*.—Stability with reference to the lateral axis.
- *Statical*.—In wind tunnel experiments it is found that there is a definite angle of attack such that for a greater angle or a less one the righting moments are in such a sense as to tend to make the attitude return to this angle. This holds true for a certain range of angles on each side of this definite angle; and the machine is said to possess "statical stability" through this range.

Stabilizer: Any device designed to steady the motion of aircraft.

Stagger: The amount of advance of the entering edge of the upper wing of a biplane over that of the lower, expressed as percentage of gap; it is considered positive when the upper surface is forward.

Stalling: A term describing the condition of an airplane which from any cause has lost the relative speed necessary for control.

Statoscope: An instrument to detect the existence of a small rate of ascent or descent, principally used in ballooning.

Stay: A wire, rope, or the like used as a tie piece to hold parts together, or to contribute stiffness; for example, the stays of the wing and body trussing.

Step: A break in the form of the bottom of a float.

Stream-line flow: A term in hydromechanics to describe the condition of continuous flow of a fluid, as distinguished from eddying flow.

Stream-line shape: A shape intended to avoid eddying and to preserve stream-line flow.

Strut: A compression member of a truss frame; for instance, the vertical members of the wing truss of a biplane.

Suspension band: The band around a balloon to which are attached the basket and the main bridle suspensions.

Suspension bar: The bar used for the concentration of basket suspension ropes in captive balloons.

Sweep back: The horizontal angle between the lateral axis of an airplane and the entering edge of the main planes.

Tail: The rear portion of an aircraft, to which are usually attached rudders, elevators, stabilizers, and fins.

Tail cups: The steadying device attached at the rear of certain types of elongated captive bolloons.

Thimble: An elongated metal eye spliced in the end of a rope or cable.

Tractor: See Airplane.

Trailing edge: The rearmost edge of an aerofoil or propeller blade.

Triplane: A form of airplane whose main supporting surface is divided into three parts, superimposed.

Truss: The framing by which the wing loads are transmitted to the body; comprises struts, stays, and spars.

Undercarriage: See Landing gear.

Warp: To change the form of the wing by twisting it.

Wash out: A permanent warp of an aerofoil such that the angle of attack decreases toward the wing tips.

Weight: Gross. See Load, full.

Wings: The main supporting surfaces of an airplane.

Wing flap: See Aileron.

Wing loading: The weight carried per unit area of supporting surface.

Wing mast: The mast structure projecting above the wing, to which the top load wires are attached.

Wing rib: A fore-and-aft member of the wing structure used to support the covering and to give the wing section its form.

Wing spar or wing beam: A transverse member of the wing structure.

Yaw: To swing off the course about the vertical axis.

- *Angle of*.—The temporary angular deviation of the fore-and-aft axis from the course.

by the handicraft of the workman. In good modern jig practice, hand tools are entirely prohibited. The reason for this is that all parts, however small, should be made in their own particular jigs. If at any time it is discovered that a part does not fit correctly into its proper place, hand tools must not be used to correct the deficiency, but rather the fault which caused the defect must be eliminated from the worn or incorrect jig originally used to make that part.

A description of the whole art of the design of jigs and fixtures would require a voluminous treatise. As neither space nor time will permit of such full treatment here, it is proposed to summarize in the form of a running commentary a few of the main points that are often overlooked.

Saw Mill Jigs

A great deal of subsequent work can be saved if the preliminary rough sawing is done to close limits of the finished sizes. This can be accomplished by means of suitable jigs, which can be clamped on to the timber and serve as guides. During sawing, the guiding portions would be kept by the sawyer in contact with fences on the saw bench.

Spindling Machines

With the aid of carefully thought out jigs, these machines are invaluable to an aeroplane manufacturer. At the present time they are not utilized to anything like the extent to which they should be for lack of jigs. Preferably suitable ball races should be fixed on the projecting portions of the spindles for the jigs to bear against and thus reduce jig wear to a minimum. As far as is feasible, safety tool holders should be employed, for not only are they a protection to the operator, but they also facilitate the setting of the tool and the cutting edge is more easily arranged at the best cutting angle.

No hand tool work should be permitted in an aeroplane factory. Hence, all parts, even the smallest, should be made on spindling machines of some kind. With the aid of proper jigs it is really wonderful what work can be done in this direction. For light work it is not essential to employ the heavy standard spindling machines, as some manufacturers have successfully employed short ball bearing shafts, which have been fixed in a vertical position on stout wood framework.

Jigs for small parts should be so constructed that several pieces may be spindled at the same time; if the clamping arrangements are adequate the several pieces will lie flat and the finished shapes will be identical.

Color Scheme

These various small pieces should be stored in separate boxes or bins. All the boxes or bins containing the pieces for one particular component should be painted a distinctive color or combination of colors. The jig in which these parts are assembled should be painted the same color or combination of colors. This materially assists the operatives, and is a scheme which might be standardized throughtout the country.

Tools and Gauges

All special form cutters should be made to designs prepared in the jig and fixture drawing office. This will ensure all sub-contractors turning out identical parts. The tools should be set in the various machines to gauges and not to pattern parts. These gauges should be designed in the drawing office. Then all sub-contractors would have to set their tools to perform exactly the same work and incidentally save considerable time.

All cutters and gauges should be made in quantities in a tool-room, similar to an engineering works tool-room. An operator should not be allowed to do anything to a tool more than just stone it up in position. The tools should be set in the spindle to a gauge and not to a pattern part. By this means any number of sub-contractors will be in a better position to produce identical parts.

All tools and gauges should be made to special drawings and not according to the operator's ideas in the various shops. Thus, a complete record is kept of how to do a job, and it is an easy thing to start a new workman in the way he should go.

If proposed use is made of jigs, tools and gauges, it will be impossible to turn out work that is not correct, although the worker may have no experience of aeroplane work at all.

Special Tool Steels

.It is put forward that undoubtedly superior steels should be employed for wood working than those now utilized. This would permit of the machine tools operating at higher speeds than they do at present, which would result both in a bigger output and better work. Machines which now run at 5,000 revolutions per minute could be speeded up to something like 7,000 revolutions per minute. It is true that this would shorten the life of each machine, but much better and quicker than work would be done.

Special Shop to Make Jigs, Tools and Gauges

It is suggested that since most aeroplane sub-contractors have no tool-room facilities, a special jig and tool shop should be run in connection with the drawing office to manufacture all tools, jigs, etc., which sub-contractors are not in a position to make for themselves. Then tools and gauges could be turned out in quantities and sub-contractors would be assured of a good supply to assist them in their efforts to attain maximum production.

Much could certainly be learned from metal milling practice that could advantageously be applied to the operation of spindling machines. In fact, inverted spindle machines with face cutters are already in use. Horizontal spindles could also undoubtedly be employed with advantage.

URGE ALLIED AIR GENERALISSIMO

THE allied control of the air becomes more marked from day to day. It had a great part in checking the German offensive plans. Now the allied aerial forces are so much stronger than those of the enemy, this superiority must be maintained. The best way to accomplish this, is to make an experienced and capable man commander of all the allied aviation organizations, just as General Foch commands all the allied land forces. General Mallelere, writing in the Paris *Temps* on the various offensive arms, speaks at length of the future role of aviation, saying in part:

"It does not seem as if the Germans obtained from aviation what they expected for their offensive. Perhaps they could not expect more. We now know that at least on the battlefield Franco-British aviation played almost the role of salvation. In co-operation with the rapid intervention of French troops in the breach caused by the retreat of the Fifth British Army, and on retarding the advance of the enemy columns by means of its machine guns and bombs it confirmed the part which the airplane can play in a battle even at a low altitude over the combatants.

"But aviation, whose role has been and is so great in this war, is marked by much greater and more efficacious action.

"Aviation has co-operated in the war of attrition and also in various offensive operations. Until the end of 1917 there was no aerial strategy. Aerial strategy comprises attacks on and destruction of the enemy's vital centres—namely, munition factories, mining localities, blast furnaces, large railway depots, bridges, military establishments, and so on, and demoralization of populations believing themselves safe from the danger of invasion. Regarding Germany our aerial tactics should comprise invasion of enemy territories in reciprocity for our invaded and devastated countries. But it would be a great error to consider these solely in the light of reprisals. It is not a question of responding to Germany's barbarous proceedings. We have been compelled to oppose poisonous gas with poisonous gas.

"We must look at war as it is according to the methods of German militarism. Armed Germany is an entirely belligerent nation. Labor outside of the zone of military operations contributes to maintain the strength of the combatants. Whether in the factory or on the land, every one fights. The blockade starves both civilians and soldiers. Aerial warfare must complete the combined work of blockade and battle. If one wants to reach an end he must not stick at the means. Our end is to disarm Germany and make it impossible for it to resume its policy of conquest. The first duty of aviation is to cover the entire zone of operations and to contribute to the battle by the destruction of enemy reinforcements and supplies.

"The second is to aim at the enemy country.

"This strategy of attack and invasion consists of intensive bombardments continued day and night. Bombardment is the final object of aviation."

General Mallelere describes the necessary conduct of aerial warfare and mentions some of the objective points within the enemy territory which may be effectively bombarded—namely, the Lorraine mining regions between the rivers Moselle and Rhine, which have often been raided in past months by Franco-British squadrons; the Rhine valley, teeming with populous and industrial cities, the Main valley, with Frankfort, Karlsruhe, and Stuttgart; the Bavarian plains, with Munich and also Cologne, Wilhelmshaven, Cuxhaven, Kiel and other points accessible to allied hydroaeroplane squadrons. The writer concludes:

"One may judge of the immense result of this aerial strategy by the emotion, not to say terror, created in the Rhenish region by the recent bombardments executed by Franco-British squadrons. When the squadrons incessantly renew their attacks and transforms the Rhine valley into an inferno, other cries of distress will be heard from the enemy. Germany will then feel the effects of this iron fire which it wished to make an instruments of its determination. Such a programme requires thousands of machines. We must and will have them."

PRESIDENT WILSON ORDERS JUDICIAL AIRCRAFT INVESTIGATION

CLIMAX REACHED IN AIRCRAFT INVESTIGATION

FOLLOWING a period of charges and counter charges regarding the aircraft situation, President Wilson turned the whole matter over to Attorney-General Gregory, who was instructed to make a thorough investigation of the "wholesale charges" in regard to the production of aircraft made by Gutzon Borglum, the sculptor.

Another sensational feature was added to the case when it became known that Major Gen. George O. Squier, Chief Signal Officer of the Army, who is accused by Mr. Borglum of hampering the work of investigation undertaken by the latter, had made a request for a military court of inquiry. A court of inquiry which is a sort of military grand jury, which, after investigation, recommends whether court-martial proceedings are desirable. It also expresses opinions as to whether charges affecting an officer or officers are true or without merit.

The President's decision in favor of an investigation was announced after he had received from Howard Coffin, Chairman of the Aircraft Board, who had been South, a telegram urging that an official inquiry be made "in order that the reputations of innocent men may not be ruined."

The announcement of the President's decision was made when the White House on May 6th gave out copies of messages exchanged between President Wilson and Chairman Coffin and a copy of a letter sent by President Wilson to Senator Thomas of the Military Affairs Committee, in which the President expressed the hope that "the matter will be treated as one for searching official investigation by the constituted authorities of the Government" and said that "every instrumentality at the disposal of the Department of Justice will be used to investigate and pursue charges of dishonesty or malversation of any kind."

Letters to Borglum Also Made Public

The President also made public seven letters he had sent to Mr. Borglum or Secretary of War Baker in the last five months in connection with the investigation the sculptor was making into the aircraft production situation. These show that the President in January urged Mr. Borglum to come to Washington, lay the whole matter frankly and fully before Secretary Baker, "and by your own investigation discover the facts in this business," but in April wrote him that "I never at any time constituted you an official investigator."

Mr. Borglum conferred with members of the Senate Military Affairs Committee and furnished a list of men who, he said, could reveal information of irregularities in aeroplane production.

Senator Chamberlain, Chairman of the committee, said on May 6th that no decision had been reached as to an inquiry based on the Borglum charges. The sentiment of the committee, he added, was to allow the Department of Justice to make the investigation. Most of the members of the committee feel that the Borglum charges properly come within the scope of the department. A vote on the proposal to open an inquiry by the committee will be taken within the next few days.

Coffin Telegrams and Thomas Letter

No statement was issued at the White House in connection with the making public of the telegrams. The telegram from Chairman Coffin follows:

"DARIEN, Ga., May 4, 1918.

TO THE PRESIDENT:

Charges of dishonesty have been made against the Aircraft Board, which demand the fullest inquiry. I request and urge that an official inquiry be had in order that the reputation of innocent men may not be ruined.

HOWARD COFFIN."

Here is the President's reply:

Telegram.

"WASHINGTON, D. C., May 6, 1918.

HON. HOWARD COFFIN, Darien, Ga.

Your telegram received. You may be sure I shall co-operate in every way to prevent what you rightly foresee might happen. The Department of Justice will co-operate to the utmost in seeing that all charges are probed and the truth got at.

WOODROW WILSON."

Simultaneously with the sending of his telegram to Mr. Coffin, the President forwarded this letter to Senator Thomas:

"THE WHITE HOUSE,
WASHINGTON, May 6, 1918.

MY DEAR SENATOR:

You were kind enough to consult me the other day about the wholesale charges in regard to the production of aircraft which have been lodged by Mr. Gutzon Borglum. I take the liberty of writing you this letter in order to say more formally what I said to you then informally, namely, that every instrumentality at the disposal of the Department of Justice will be used to investigate and pursue charges of dishonesty or malversation of any kind, if the allegations made by Mr. Borglum are considered worthy of serious consideration, and I sincerely hope that the matter will be treated as one for searching official investigation by the constituted authorities of the Government. Only in this way the reputations of those whose actions have been perfectly regular and blameless be protected and the guilt, if there is any, definitely lodged where it should be lodged.

Sincerely yours,
WOODROW WILSON.

HON. CHARLES S. THOMAS, United States Senate."

The Letters to Borglum

In connection with the Borglum report, it has been freely stated that Mr. Borglum was the "President's investigator" and that his investigation had the sanction of the President. The seven letters made public by the White House throw light on this phase of the matter. The first of the letters reads:

"THE WHITE HOUSE,
WASHINGTON, December 5, 1917.

MY DEAR MR. BORGLUM:

Your letter of November twenty-second to Mr. Tumulty (the President's Private Secretary) he was kind enough to show me, and I had meant to write to you sooner about it. Of course, what you say disturbs me not a little, and I write to ask you if you will not do me the great favor of indicating as specifically as possible the weaknesses you see in our present organization in the matter of aeronautics. I would also appreciate it very warmly if you would tell me what men of practical gifts not now connected with the service of the Government you think could be serviceable to us in working towards a successful result.

Cordially and sincerly yours,
WOODROW WILSON.

MR. GUTZON BORGLUM, Stamford, Conn."

"THE WHITE HOUSE,
WASHINGTON, January 2, 1918.

MY DEAR MR. BORGLUM:

I have your letter of December 25.

Knowing the earnest and loyal purpose with which you have written me, I have conferred with the Secretary of War, and at his request and with my own hearty concurrence, I urge you to come at once to Washington, lay the whole matter frankly and fully before the Secretary, and by your own investigation discover the facts in this business. The Secretary of War assures me that he will be delighted to clothe you with full authority to get at the bottom of every situation, and that he will place at your disposal the services of Mr. Stanley King, a member of his own personal staff, if you desire to have his counsel in your inquiries. The Secretary further says that he will bring you into personal contact with General Squier, whom you doubtless already know personally, and will direct that every facility of inquiry be placed at your disposal. When you have thus investigated, if the other experts whom you suggest in your letter of December 25 still seem desirable to be appointed, you can say so to the Secretary; and, in the event of any difference of judgment between you, which seems to me impossible, I would be most happy to have a report from you personally to me on any phase of the matter which remains in the slightest degree doubtful in your mind.

Cordially yours,
WOODROW WILSON.

MR. GUTZON BORGLUM, Borgland, Stamford, Conn."

Report Referred to Baker

Mr. Borglum's report was completed in January and submitted to the President, who on February 1 sent it to Secretary Baker, with this note:

"THE WHITE HOUSE,
WASHINGTON, February 1, 1918.

MY DEAR BAKER:

Here is Mr. Borglum's preliminary report. Is there not some one entirely disconnected from aeronautics and from those who are prominent in carrying out the aeroplane program whom you can ask to go over this thing with an unbiased mind and give us his naive impressions of it? There may be something worthy of our consideration and suggestions worthy to be adopted.

Cordially and sincerely yours,
WOODROW WILSON.

HON. NEWTON D. BAKER, Secretary of War."

A letter written on March 15 to Mr. Borglum by the President read:

"THE WHITE HOUSE,
WASHINGTON, March 15, 1918.

MY DEAR MR. BORGLUM:

I have your letter of March 11 and thank you for it. I am writing in great haste to say that the whole aircraft matter is undergoing a very thorough review.

In haste,

Sincerely yours,
WOODROW WILSON.

MR. GUTZON BORGLUM, Stamford, Conn."

At the end of March President Wilson sent this letter to Mr. Borglum:

"THE WHITE HOUSE,
WASHINGTON, March 29, 1918.

MY DEAR MR. BORGLUM:

In view of your telegram of yesterday I am very glad to explain to you what my telegram to you meant. It meant this, that I have now instituted a very systematic inquiry into the whole aviation situation and think it wise that all processes of investigation should be in the charge and under the direction of the gentlemen to whom I have committed this task. I have placed at their disposal the material you were kind enough to furnish me with and can assure you that they will go to the bottom of it all.

I know your own judgment will approve of this.

Sincerely yours,
WOODROW WILSON.

MR. GUTZON BORGLUM, Hotel Pontchartrain, Detroit, Mich."

On April 4 the President sent this communication to Mr. Borglum:

"THE WHITE HOUSE,
WASHINGTON, April 4, 1918.

MY DEAR MR. BORGLUM:

Thank you very much for your letter of yesterday. You may be sure that the whole matter will be and is being gone into to the bottom.

Cordially and sincerely yours,
WOODROW WILSON.

MR. GUTZON BORGLUM, care Metropolitan Club, Washington, D. C."

Not an Official Investigator

The seventh of the letters made public read:

"The White House,
Washington, April 15, 1918.

My Dear Mr. Borglum:

I am afraid that you have for some time been under a serious misapprehension. You call my attention to the fact that you were not supplied with suitable expert assistance in the investigation which you, of your own motion, undertook of the aircraft production.

You will remember that at the beginning you wrote to me saying that you feared and believed that there were very serious errors not only, but serious bad practice, in the aircraft production, and after consulting with the Secretary of War I wrote you that, if it was your impression, you were, of course, at liberty to examine any evidence that was in our possession. *I never at any time constituted you an official investigator. I merely gave you the right to look into the matter of your own motion, and I am sure that the letter which the Secretary of War provided you with he gave you with the same purpose and idea. We have wished at every point to assist you and to make possible for you what you wished to do, but we have at no time regarded you as the official representative of the Administration in making the investigation. If I had so regarded you, I would, of course, have supplied you with such assistance as you feel you have lacked.*

You will understand, of course, that I write this in the most cordial way and only because it is evident from your last letter that you have been laboring under a misapprehension.

I hope that you will be willing and that you feel that it is your duty to put at the disposal of those whom I have constituted official investigators all the evidence that may be in your possession.

Cordially and sincerely yours,
Woodrow Wilson.

Mr. Gutzon Borglum, Metropolitan Club, Washington, D. C."

The italicized matter in the above letter represents, according to the Committee on Public Information, matter underscored in copies of the letter furnished by the White House.

Mr. Borglum gave to the press two letters which he had sent to President Wilson, one of them written May 6th, after the announcement that the President had ordered an investigation of the aircraft situation by the Attorney General. The other was dated January 21.

In both letters Mr. Borglum contended that he had been hampered in his work of investigation and had been obliged to conduct his inquiry without aid. He accused the President of not having given him proper help. Among his allegations were that "officials who should have aided me had intercommunicated, attempted to mislead me and block every avenue I approached." He charged that General Squier had hindered him, and that he got no assistance when he told the Secretary of War of his difficulties.

The letter written to the President by Mr. Borglum May 6th follows:

Text of Mr. Borglum's Letter

"Washington, D. C., May 6, 1918.

Hon. Woodrow Wilson, President U. S. A.:

My Dear Mr. President:

It is something more than a shock that I noticed today the publicity which I could hardly interpret in a friendly manner, considering the order of the statements given and the meaning of your empowering letter to me, and I am taking, therefore, the only course open to me, that of addressing to you a reply, republishing your empowering letter, together with my first letter to you, accompanying my first review of the aeronautic situation.

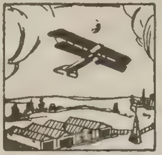
In this I refer to the difficulties I met with in carrying out your wishes that "I go to the bottom of this business." Beyond that I spared you the record of petty intrigue, espionage, and a general system of official bullying that is carried on by, if not at the direction of, great departmental officials, certainly with their knowledge and approval. I had not been in the office assigned to me in the War Department forty-eight hours before I met with the intrigue of that department. Requisitions that I made for data brought untrue or valueless reports, and Mr. Stanley King, whom you had named to be my aid, and whom Assistant Secretary of War had turned over to assist me, began to systematically block the work I was undertaking, to the extent even of threatening witnesses who came to my office, Room 225, War Department, to give me information, and warned that they would give information to me at their peril. General Squier acted in a like manner, and every official that I approached and from whom I had the right to receive aid and courtesy, had, apparently under general instructions, entered into a common conspiracy to deceive, to mislead, and prevent learning the truth about the aeronautic situation. I do not presume to give the reason for this, although I fully realize the sources the periodical statements, false in contents and in purpose, emanating from the War Department regarding aeronautics, would not look with favor upon any inquiry that dealt with the true situation, and so within a week, on January — I abandoned the War Office and secured an office without the building that my investigation might be less prejudiced, and might get more accurately and quickly at the truth of the situation. Nor did I fail to inform Mr. Baker of the serious condition that prevailed, and demanded correction, without avail; this constituted my first grievous offense—I had demonstrated *I* at least would not WHITEWASH. The reports that I sent to you were true, and if they erred at all, they were not strong enough in statement, which a subsequent inquiry has proven and placed amply before the public.

My investigation was a preliminary inquiry. It was so agreed between us, and, further, should I deem it necessary to have two assistant experts they would be appointed, and if there was any difference in opinion between Mr. Baker and myself, you agreed that I should deal directly with you. These experts never were appointed, your promise was not kept and my request, frequently urged upon you, only brought the appointment of men without knowledge, without information and wholly unfitted to inquire in a subject that had failed largely because it was conducted without information and knowledge; that is, had there been a few informed men even remotely connected with that huge appropriation, a few planes would have reached Europe.

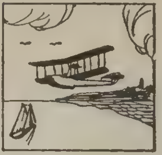
I have pleaded for investigation, consistently and persistently, and I still plead for investigation. I have asked for nothing else but investigation, I have given months and months of valuable time, hoping that investigation would finally come. There has been a great deal of talk and a great deal of noise, but for some strange unaccountable reason, it is impossible to get official action that will really investigate the aeronautic group. The nation knows its billions, or such part of it as they could possibly manage to use, is gone. The nation and all of our boys know that there no planes to protect them, although Colonel Deeds told the National Press Association recently in great confidence that "we had 1,200 fliers with 1,200 planes, all ours, flying over our lines." An officer who has arrived in this country within the week, straight from our troops, informs me we have less than twenty. That they are French school planes. That they are not allowed near the German lines, and that our single balloon is hastily pulled down out of danger as the enemy planes appear.

I was among the first to call official attention to specific weaknesses in the Liberty motor. In spite of the resentment at the time the justice of these criticisms has been admitted by the Chairman of the Aircraft Board, correction made, and they are rebuilding the engines on those lines at this moment, but I had sinned in daring to criticise, and, as some of your most important and prominent associates in our Government have said, Borglum "blundered in telling the truth." I have said the Aero Department is full of profiteering, that hundreds of millions have gone, that factories have been created where there were no factories necessary, and contracts to the extent of fifty millions given to men who had neither rhyme nor reason for the remotest connection with the emergency of aeroplane production, but who had the pull of deeds and who are still floundering in their ignorance and incompetency, unable and incapable of fulfilling their contracts, still drawing under the cost plus system upon the Treasury of the nation. I have said that aeronautic men of ability of the nation have been snubbed and ignored, unemployed, and that factories, or nuclei of factories, that could have been developed into producing institutions, who knew the art of aeroplane building, are even at this writing without the slightest consideration by the group who dealt out the colossal funds for their purpose. I have said the Liberty motors should never have been undertaken until other available motors had been put in production sufficient for an emergency fleet of aeroplanes built that our army could have used when it was ready, and I have said that this was not done because the group who were interested in the production of the Liberty motor were interested in the establishing and controlling of the monopoly of that engine for aeronautic work, and were not interested or at least have never shown interest that protected the troops they were charged to protect. I have also said that there has been gross profiteering in the methods of contracts, and that millions could be saved if the Government would act quickly, even by the consent of the manufacturers themselves. I have pointed out that although the engine was still an experiment there were no planes, there can be no planes and there will be no planes until an engine or the engine is done and a perfect and a completed thing, so the country "believed that when the Liberty motor would reach its production we would have thousands

(*Continued on page* 450)



THE NEWS OF THE WEEK



Another Billion to Build Aircraft Is Asked for Army

Washington, May 6.—A billion-dollar appropriation for aircraft production was asked of Congress by the War Department. This would add to the $640,000,000 appropriation already made and expended.

The estimate was presented to the House Military Committee by Major General March, acting chief of staff, and other officers. At the Congressional hearings it was stated by Signal Corps officials that the $740,000,000 apportioned for aviation has been expended as follows:

The War Department has expended $307,000,000 for aeroplanes as follows:

There is an unexpected balance now on hand of $433,000,000.

Of the unexpended balance, all is covered by contract, and additional contracts have been let for machines and other equipment which provide for expenditures of $148,000,000 beyond the appropriation.

The money already expended has been used as follows:

For engines and aeroplanes and general machine equipment..........	$163,000,000
For hangars and the acquirement of aviation fields in this country....	42,000,000
For aviation fields and other purposes in France.................	31,000,000
For gas balloons.................	5,000,000

There is $31,000,000 in the hands of the disbursing agents and not reported at the hearing.

The balance has been spent for miscellaneous aviation work, for experiments and other general expenses connected with the program.

The Government has ordered 14,000 foreign planes, and 1,800 have been delivered, he said, while 8,000 foreign engines have been contracted for, the deliveries amounting to fewer than 1,500.

There are between 1,200 and 1,400 aviators actually flying with the American forces on the Western front.

There are 5,000 men physically fit and ready to enter the service, while there are 15,000 flying and non-flying aviation service officers in the United States and France.

In the Signal Corps to-day there are 133,000 men and officers, which exceeds the strength of the regular army when this country entered the war.

Major Oscar Brindley Accident Victim

Dayton, O.—Major Oscar A. Brindley and Colonel Damm, two expert aviators from McCook flying field, Dayton, O., met death as a result of a 400 foot fall, which their machine took while making a turn in the air.

Lieut. Lloyd S. Allen, a member of the Yale Club and the Aero Club of America, was killed in a practice flight when he lost control of his machine and crashed into one of the school buildings of Wilbur Wright Feld, near Dayton.

Rolls-Royce Capital Doubled

London, April 20.—At the annual meeting of Rolls-Royce, Ltd., held recently, it was voted to increase the capital from $950,000 to $1,900,000, subject to the approval of the British Treasury. The new shares are to be issued against a naccumulated reserve of $1,088,000. A cash dividend of 10 per cent for the year, less income tax, was also declared.

S. A. E. to Exhibit Aeroplane Engines at Summer Meeting

Dayton.—Plans have been perfected for the two-day summer meeting of the Society of Automotive Engineers, to be held in Dayton, on June 17th and 18th. The trend of the meetings will be less technical than heretofore, it being deemed more important to lay stress with popular papers dealing with new designs of automotive apparatus for the war.

There will be on exhibition various aviation engines, among which are all of the German types, such as the Mercedes and Benz, Renault, Gnome, Garrone and Hispano-Suiza motors, as well as such British motors as the Rolls-Royce, Sunbeam and others. Several captured German aeroplanes, as well as standard French and British planes will be in evidence.

Among other exhibits of special interest will be demonstrations of machines for manufacturing aeroplane propellers in operation. There will be demonstrations, with explanation, of synchronizing machine guns which fire between the blades of propellers on fighting planes. Formation flying will be executed by various planes, over Triangle Park, where the meetings will be held.

The Engineering Council's War Committee of Technical Societies

Major Henry Abbey, Jr. is Commanding Officer at Chanute Field, Rantoul, Ill.

The War Committee of Technical Societies, of which Mr. David W. Brunton is chairman, was founded by the Engineering Council in July, 1917, and represented at the time of its formation the four founder societies. The Committee was formed for the purpose of stimulating members of the various technical societies into giving consideration to the matter of the invention of war apparatus, with the object of assisting the Army and Navy. As a definite means of effecting this object, the Committee was given the work of procuring problems—especially difficult problems—from the Army and Navy for presentation to the membership of the societies for solution.

For several months the Committee has been coöperating actively with the Naval Consulting Board, and now has offices and a meeting room in the New York office of the Naval Consulting Board, 15 Park Row. The Committee now has the following membership:

American Society of Civil Engineers: Nelson P. Lewis, Major James M. Boyle. American Institute of Electrical Engineers: Harold W. Buck, A. S. McAllister; American Society of Mechanical Engineers: A. M. Greene, Jr., R. N. Inglis. American Institute of Mining Engineers: David W. Brunton, Edmund B. Kirby. American Gas Institute: Dana D. Barnum, F. C. Uhlig. American Electrochemical Society: Joseph Bijur, Dr. Chas. A. Doremus. Illuminating Engineering Society: Louis B. Marks, Preston S. Millar. Mining and Metallurgical Society of America: Christopher R. Corning, George C. Stone. American Society of Refrigerating Engineers: Henry Torrance, F. E. Matthews. American Institute of Chemical Engineers: Charles F. McKenna, Frank E. Dodge. American Chemical Society: (Coöperating) Dr. Chas. Baskerville, W. D. Richardson.

Lieut. Flachaire Flies from New York to Pittsburgh

Pittsburgh, May 5th—Lieutenant Georges Flachaire, the famous French pilot and "ace," flew his Spad machine from Mineola to Pittsburgh. He left Mineola, Long Island, on the afternoon of May 3rd, flying over Bridgeport, New York City, Jersey City, Trenton and Philadelphia, dropping Liberty Loan literature on the way. Stops were made at Harrisburg, Port Royal and Altoona. The last lap of the journey, from Altoona, Pa., to Pittsburgh, was accomplished in very good time, Lieutenant Flachaire leaving Altoona at 4:30 P. M. May 5th, and arriving at Carnegie Institute of Technology aviation field at 6 P. M. of the same day.

Goodyear Dirigible Thrills Ohians

Akron, O.—One of the dirigibles being manufactured for the United States Government by the Goodyear Tire & Rubber Company of Akron, Ohio, flew from that Goodyear Company's field at Akron to Cleveland.

The big airship gracefully manoeuvred over the city at a height of about 500 feet, and dropped aerial bombs on the city, containing Liberty Loan literature, reminding the populace below that only through liberal support of the present third Liberty Loan, thereby providing the means for vigorously prosecuting the war, can we hope to keep our shores free from enemy Zeppelins.

The appearance of the big dirigible was announced by signals similar to those used in English and French cities. Rapid fire guns installed on the Public Square sounded the first alarm, followed by the continuous shrieking steam whistles. The only feature omitted was that of the clanging bells of motor fire apparatus, accompanying the repeated cries of "take cover."

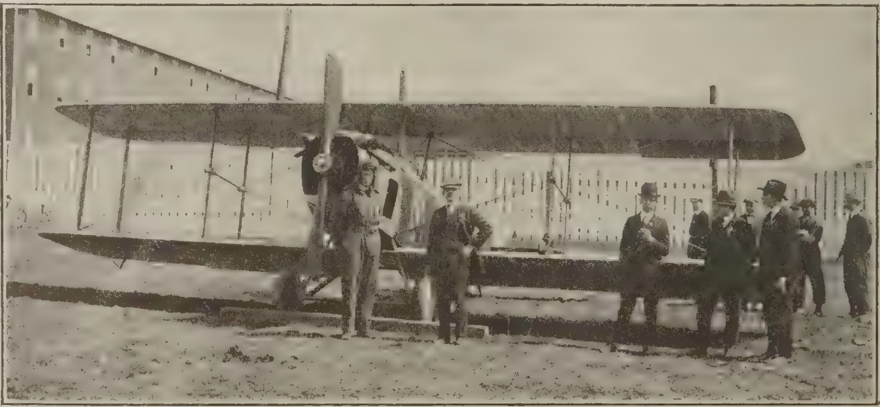
The airship, after performing its mission of furnishing visible evidence of what the government is doing in the way of providing adequate aerial scouting equipment, veered off to the south and in another hour was resting safely, back in its hangar. The entire trip lasted about three hours.

Colors for O. R. T. C. Organization

The following order amending General Orders No. 49 has been issued by the War Department:

Educational institutions, at which units of the Reserve Officers' Training Corps are established, are authorized to provide for the use of such units, colors and standards conforming to those prescribed by Article XXVIII, Army Regulations, 1913, for corresponding units of the Army, except that the seal or insignia of the institution shall be used in lieu of the coat of arms of the United States, and that, on the scroll, in lieu of the inscription prescribed for Army units, there shall be inscribed the name of the institution at which the unit of the Reserve Officers' Training Corps is established.

The provisions of the article referred to will, whenever applicable, govern the use of these colors and standards.



A new Standard speed scout, which flew from the Standard factory at Elizabeth, N. J., to aid the Liberty Loan drive in New York City

Through the efforts of these men (from left to right), H. W. Kavel, Acting director, Dunwoody Institute; W. H. Bovey, President of the Board of Trustees; Lieut. E. A. Hadeen, commanding original aviation detachment at Minneapolis, and W. F. Brooks, President of the Minneapolis Aero Club, one of the largest aviation training schools has been established in Minneapolis

Chanute Field News

Five aeroplanes from the Chanute flying field were used in the campaign for the Third Liberty Loan through the Illinois corn belt on Friday, April 26. The planes were used at the request of the University of Illinois, which supplied the circulars which were used to bomb the towns in central Illinois. After leaving Rantoul, the flyers went to Champaign, then Decatur and then Taylorville, where they made a landing and participated in the big Christian County demonstration.

Girl to Resign from Motor Transport Service

Washington.—Chirstian Girl, having practically completed his duties in Washington as Director of Motor Transport Service for the Quartermaster Corps, is expected to resign in the near future. Mr. Girl came to Washington last fall to take charge of engineering, purchase, procurement and maintenance of the standardized war trucks, and has carried his work to the quantity production stage.

Height at Which Sounds Can Be Heard

In one of his journals, Camille Flammarion gives the heights at which sounds from the earth are heard from balloons. The shout of a man was heart distinctly at the height of 1,600 feet, the sharp note of a mole-cricket at 2,500 feet, and the croaking of frogs in a morass at 3,000 feet. At 3,255 feet a man's voice and the rolling of a cart were distinguished; at 4,550 feet the roll of a drum and the music of an orchestra; at 5,000 the crowing of a cock, the sound of a church bell, and sometimes the shouting of men and women. Nine hundred feet higher still he heard the report of a musket and the barking of a dog. The noise of a railway train penetrated to a height of 8,200 feet, and the whistle of a locomotive engine to nearly 10,000 feet.

The Aero Club of the Northwest

For the purpose of disseminating information concerning aviation throughout the Northwest, the Aero Club of the Northwest has established quarters at 405 University Street, Seattle, Washington. A library will be maintained for the free use of the public, where there will be kept on file the leading French, English, and American magazines dealing with the latest developments in aviation. Information will also be on file for those desiring to enter the aviation corps of either the army or the navy. People throughout this section of the country are urged to make use of this opportunity.

Alderman Collins Joins the Aviation Corps

William T. Collins, Tammany Alderman from the Twelfth Aldermanic District, who waived his right to exemption from the draft act, enlisted recently in the Aviation Corps. Collins had a right to exemption because he held an elective office, but he asked permission to join the Aviation Corps. Inasmuch as he is over thirty years old, he was required to get special permission from the Signal Corps in Washington. Until called to service he will train under Capt. George Morris, of Company F of the Seventy-first Regiment, N. Y. G.

Alderman Collins will not resign his seat in the Board, as he announced last week he planned to do. He has found that he can remain a member until the expiration of his term on December 31, 1919. This will put an end to the plan of his fellow members to name his wife to the Board to fill the vacancy which her husband's resignation would have caused.

Official List of American Aces

PARIS, April 27.—The standing of American aviators based on the number of adversaries shot down to date follows:

Major Raoul Lufbery, 18; Major William Thaw, 5; Lieutenant Frank Baer, 5; Sergeant Baylies, 5; Captain Charles Biddle, 2 and Sergeant Vernon Booth, Sergeant August Grebore, Second Lieutenant Henry Grendelass, Sergeant Thomas Hitchcock, Jr. (now a prisoner); Lieutenant Friest Larner, Sergeant David Putnam, Sergeant W. A. Wellman, Lieutenant Allan Winslow and Lieutenant Douglas Campbell, one each.

Gerard Urges Aerial Offensive

In an address at the dedication of the Y. M. C. A. Liberty hut at Washington, D. C., April 27th, ex-Ambassador James W. Gerard, formerly Ambassador to Germany, urged that countless American aeroplanes drop bombs over Germany until the German people realize that the great war menaces them as well as all the rest of mankind.

The appointment by the President of Charles M. Schwab as head of the shipping board and John D. Ryan in charge of the aircraft program was commended by Mr. Gerard, and he urged the adoption of the Overman bill, giving full power to the President.

At the Army Aviation Schools

Lieutenant J. B. Buchanan and Lieutenant Russell Bandy were slightly injured at Clinton, Ill., recently when their aeroplane crashed into a freight train. They are fliers from Chanute Field, Rantoul, and had been ditributing Liberty Loan literature. While passing over Clinton their rudder became unmangeable.

Major John Purroy Mitchel, former Mayor of New York has qualified as a reserve military aviator at San Diego, having performed the necessary altitude and evolutions for that rating.

Manager Bowman and Instructor Meyerhoffer, who have charge of the Riverside Aircraft Company's school of Riverside, Cal.

According to Walter Camp, Commissioner of Athletics for the Navy, David J. Yales, of New York City, will soon be appointed Director of Athletics at the Pensacola, Fla., Naval Air Station.

With Our Boys "Over There"

Lieut. G. De Forrest Larner, an American aviator, has brought down his second German aeroplane.

Flying alone he attacked the German machine, killed the observer and shot the machine down in flames, killing the pilot, according to word which has reached Washington. The action took place in the Oise River area where he was flying with the French armies on March 25. His first German machine was brought down March 18.

An American naval lieutenant took part in the air raid against the German submarine base at Zeebrugge on the Belgian coast.

The American narrowly escaped from German gunfire and German aeroplanes while bombing hostile aeroplanes and the mole in the Zeebrugge harbor.

Lieutenant Paul Frank Baer, now of the United States Flying Corps and formerly of the Lafayette Escadrille, was honored by a citation which appeared in the *Official Journal* of May 2nd. The citation follows:

"Paul Frank Baer, Lieutenant of the American Lafayette Escadrille, an American pilot engaged in the French Army, has shown himself at once a pilot of the first rank, engaging the enemy in numerous combats, in which he has always put the enemy to flight, and has downed an enemy aeroplane."

A German aeroplane was brought down in enemy territory by Capt. James Norman Hall of Colfax, Ia., and Lieut. Edward V. Rickenbacher of Columbus, O., after a battle over the American line on the Toul sector.

Italian Flier Covers 145 Miles in One Hour On Liberty Day

Washington, May 3rd—Sergt. Gino of the Italian Flying Corps, startled the people of Washington by unexpectedly appearing in the air over the parade viewing crowds who were thronging the sidewalks witnessing the Liberty Loan parade. Swiftly darting low down through the air, doing "stunts" of a breath taking character. He had just arrived from Langley Field, Virginia, covering the distance of 145 miles in one hour, that being a record for such a flight. The other day this speed wonder made the round trip between Washington and Baltimore, a distance of 74 miles in half an hour.

Woman's Naval Service Holds Dance at Plaza for Aviators

New York, May 1—Several hundred persons attended the dinner and dance, held under the auspices of the Woman's Naval Service, at Hotel Plaza, New York City, on May 4th. Mr. Henry A. Wise Wood, of the Aero Club of America, made an address of welcome, following which there was an hour of music. The income from the benefit will be devoted to purchasing athletic outfits for aviators at the camps in France.

H. P. Whitney's Son Wins Aviator's Commission

Fort Worth, Tex.—Cornelius Vanderbilt Whitney, son of Mr. and Mrs. Harry Payne Whitney of New York and great-grandson of Commodore Vanderbilt, was commissioned a Second Lietenant in the flying section of the Signal Corps on April 25th and assigned to duty at Benbrook. He has been in training for four months.

The AIRCRAFT TRADE REVIEW

N. E. J.

Wright-Martin Buys Long Island City Factory

The Wright-Martin Aircraft Corporation, which has been manufacturing Hispano-Suiza aviation motors for the French Governmen. at New Brunswick, N. J., has purchased the huge plant of the General Vehicle Company, in Long Island City, N. Y. This plant will be devoted to the manufacture of the famous Hispano-Suiza motor for the United States Government, which has placed an order for a large number of 300 horsepower motors. The plant, when worked to full capacity, requires a working force of from 6,000 to 8,000 men.

Aeroplane Mechanics' School in Detroit

Detroit, Mich.—The Michigan State Auto School of Woodward Ave., Detroit, Mich., has opened an aeroplane mechanics' course in order to train men as aviation mechanics or as production men for the aeroplane engine factories.

The course requires two months, and includes assembly, repair and operation of aeroplane engines, as well as construction and maintenance of the machine. The apparatus used for the work so far is confined to production of the Curtiss plant, including a Curtiss Model J.N.4. Students are given practical work, such as overhauling and rebuilding machines, which have been in service. One of the machines which has been repaired had been badly damaged by a nose dive, and the repair of this machine gave the students ample practice. A Roberts six-cylinder motor, which was the power plant of this plane, has also been repaired and put in running shape by the students.

The head of the aeroplane instruction faculty is a Curtiss expert. The school plans not only to turn out mechanics for war purposes, but to establish itself for the demand that will exist after the war.

Victor Talking Machine Company Gets Hydroaeroplane Contract from the Navy

Washington, April 22nd.—The Victor Talking Machine Co., of Camden, N. J., has received a government contract for hydroaeroplanes for the navy. Five thousand employees are to be engaged in the work.

Rubber Imports May Be Curtailed

Washington.—According to reliable information, the War Trade Board is about to issue an order which is intended to curtail the importation of raw rubber to this country. It is designed to create more available shipping tonnage for traffic between this country and France.

This curtailment will greatly effect the rubber tire industries, whose increasing demands have required 400 per cent. greater imports in the last five years.

It is understood that the order will refuse licenses to importers of the better grades of rubber from Java and the Far East.

Rubber imports from South America will be continued, but these will be insufficient, and it is anticipated that after the reserve rubber stocks in this country are exhausted, American tire manufacturers will be forced to produce tires of less durable material.

A Correction

It has been called to our attention that in our issue of December 31st, 1917, we stated that the "Triplex combination," referring to glass for aviators' goggles was "known as Resistal" in America and was manufactured by Strauss & Buegeleisen. This statement is not in exact accord with the facts. "Triplex" is a copyrighted trade-mark, the process used in the making of the glass is secret, and this process is covered by the Triplex-Mascart-Benedictus patents, the sole rights of which are owned in this country by the Triplex Safety Glass Corporation of America. This company is affiliated with the Societe de Verre Triplex, 13 rue des Nouettes, Paris, France, and the Triplex Safety Glass Company, 1 Albemarle Street, Piccadilly, London, England.

The Triplex Safety Glass Corporation is erecting a building 150 x 200 at Mount Vernon, New York, especially adapted for the manufacture of Triplex and designed by the English Triplex management. The American Triplex company will manufacture Triplex exactly as it is manufactured by the French and English Triplex companies and will be producing glass in two months.

Mr. Rowland Barbour, production manager, and Mr. W. J. Finlay, sales manager, have spent six months in the French and English factories, and so as to insure proper manufacture of Triplex, this company is utilizing the resources of the English and French Triplex companies both as to machinery and heads of departments, who are already in this country equipping the factory.

The Triplex Safety Glass Corporation has the backing of influential business men, the directorate being as follows: Messrs. W. E. S. Griswold, H. P. Teare, W. B. Ticknor, Charles W. Pruyn, J. W. R. Crawford, president; W. J. Finley, vice-president.

Aeroplane Tires

Uncle Sam, already the largest consumer of rubber tires, is now entering a new field that will augment his tire bills to even greater proportions. A new demand will arise from the adoption of the aeroplane as a carrier of United States mail.

Aeroplane tires have been manufactured by the B. F. Goodrich Rubber Company for over ten years. Glenn H. Curtiss was the first aeroplane manufacturer to adopt the pneumatic tire on a substantial scale. Wright Bros. used skids in their first experiments, and were slow to see the practicability of rubber tires. The plane in which Curtiss made his first long flight, the one over Lake Erie, was equipped with Goodrich aeroplane tires. Tires used in aviation evolved from the bicycle tire. The first tires used by Curtiss at Hammondsport, N. Y., were bicycle tires.

Tires such as will be used on the postal planes are of special construction and differ in many respects from automobile tires. Aeroplane tires are built upon the principle of least weight with the greatest strength—they must lend great speed in starting, have exceptional strength to withstand hard, direct blows and side shocks in landing, and must be unusually resilient in order to absorb shocks evenly. Aeroplane tires have no thick tread and have no breaker strip, two essential features of auto tires. Rubber of exceptional quality is used in the side wall and tread, giving maximum flexibility.

The Modern Fiat Engine Test Shop

The Fiat Company, of Torino, Italy, which is constructing a large proportion of the aircraft motors used by the Italian Government, submits its motors to the most exacting tests before they are put into service. For this purpose, a very modern and efficient testing shop has been erected. The test benches are arranged in parallel rows and series of twelve, each bench being independent and arranged on an armoured concrete foundation with a bank of sand around it to absorb vibration. The exhausts discharge into a large underground concrete main, which is provided with a powerful exhaust fan. Not only does this arrangement render the shop free of disagreeable odors, but the noise of the motors is thereby greatly reduced. The fuel is contained in underground tanks and is connected to the carburetor by means of flexible tubing.

The new, enlarged Glenn L. Martin Aircraft factory, in Cleveland, is now practically ready for occupancy

750 h.p. Sunbeam

Not content with having advanced the Sunbeam-Coatalen engine from 150 h.p. to 500 h.p. maximum the manufacturers are now experimenting with the object of producing engines of 750 h.p. on a weight basis not exceeding 2.5 lbs. per h.p. The attempt may be expected to elicit the familiar arguments respecting the comparative advantages and disadvantages of using one big motor, or of relying upon two or more for the same totality of power. It is a tribute of merit, as well as an objection, that high efficiency engines need high efficiency engineers to put them together, and that they are only possible of manufacture when the very best materials are available.

Estimate of Transport Cost

M. Soreau, vice-president of the French Aero Club, has struck out into original calculations, the result being that he differs from the formulæ usually accepted as the cost of aerial transport. Usually it is assumed that a big machine, by reason of the larger quantity of goods or mail carried, will perform the work more cheaply than a small machine will. M. Soreau fails to follow that assumption. He stated that a special type of two-seater of 2,170 kilos could carry over the Paris-London route 400 kilos of letters. That part of the matter seems simple. Then he calculates that a smaller machine of 1,440 kilos could carry 280 kilos, the lesser weight carried being more than offset by the saving in expenses. As his scale of calculations is not at hand one cannot verify the items. It amounts to this, that the smaller machine could carry 3,080 kilos of letters compared with 2,800 carried at the same cost by the larger machine. His paper was read at a meeting of the French Academy of Sciences, and the meeting also discussed projects of aerial postal communication with Asia and Africa after the war.

Triplex

A finely illustrated booklet on the merit of "Triplex" has just been issued by the Triplex Safety Glass Company, Ltd., 1 Albemarle Street, W. From this publication we gather that the manufacture of glass was first discovered by the Phœnicians in Palestine about the year 700 B. C., and improved by the Assyrians. The Romans made great headway with glassware, but it was not until the 20th Century that unbreakable glass was invented. Triplex glass is both transparent and fracture proof. It is claimed to be non-shattering, non-splintering and, in short, the ideal glass for motorists, airmen and those requiring protection from danger.

International Air Traffic Company

According to the *Neue Freie Presse,* January 4, a new company has been formed in Austria-Hungary styled the International Air Traffic Company (Internationale Luftverkehr - Aktiengesellschaft, abbreviated "Ilag"). It is intended that the "Ilag" shall at first undertake the conveyance of letters and parcels on the route Hamburg - Berlin - Dresden - Vienna - Budapest - Belgrade-Sofia-Constantinople. From points in this main line numerous branch lines will run to the most important cities and traffic centers of Germany and Austria-Hungary, so that, according to present intentions, the whole of Central Europe will be covered, at no very distant date, with a close network of air lines. Passengers will be carried as well as postal matter.

Steps are to be taken to form separate companies in Austria and Hungary. The promoters are in touch with interests in Germany, so that there, too, a company will shortly be formed in close connection with the Austrian and Hungarian enterprises. The Austrian and Hungarian post-office administration, even before the war, had begun negotiations for a contract for postal dispatch, which can only be definitely concluded when the "Ilag" is ready to commence its service; negotiations, however, with municipal authorities have already commenced there with a view to providing landing places suitably equipped in all the towns covered by the new air service.

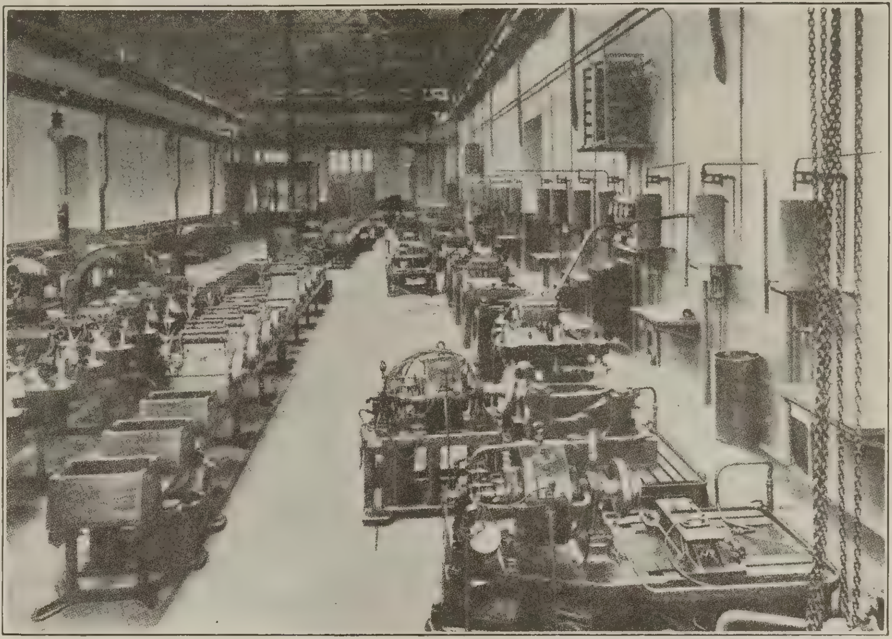
Meanwhile the legal committee of the Hungarian Aero Association has made an agreement with the Austrian Aero Club and the Imperial German Aero Club of Berlin that the contemplated interassociation conference for the purpose of establishing uniform laws for the air, to which those in Bulgaria, Turkey and Poland interested in the matter, are to be invited, shall take place in Budapest in the second half of 1918.

Personal Pars

L. R. Scafe, for two and a half years secretary and treasurer of the Saxon Motor Car Co., has been appointed comptroller of the Dayton-Wright Aeroplane Co., Dayton, Ohio.

Howard Taylor, who for some years has been chief electrical and mechanical engineer of the Spanish River Pulp and Paper Co.'s plants, with headquarters at the Soo, has resigned to become consulting engineer with the Dayton-Wright Aeroplane Co., at Dayton, O.

Rodney Chase, now in the naval aviation service, is engaged to Miss Grace P. Hendricks, of New York City. Mr. Chase was a member of the Yale class of 1920 before his enlistment.



The modern testing plant of the Fiat Company. The exhaust gases and fuel supply are conducted by underground piping

ALL BRITISH FLYERS IN ROYAL AIR FORCE

ALL officers of the British Royal Naval Air Service and Royal Flying Corps will be granted temporary commissions in the Royal Air Force, according to an order recently published in the official London *Gazette.* Another order provides that for the duration of the war khaki will be worn as service dress. The orders are as follows:

All officers serving with the Royal Naval Air Service and Royal Flying Corps on the 31st March, 1918, or in connection with those services in certain Government departments, in other than the undermentioned capacities, are granted temporary commissions in the Royal Air Force, with effect from the 1st April, 1918, in ranks which will appear in the Royal Air Force list.

In view of the special circumstances incident to the inception of the Royal Air Force these ranks must be regarded as subject to revision as circumstances may require until confirmed by the actual issue of the Commission.

The exceptions are as follows:

Certain officers of the Royal Navy whose services are only lent temporarily to the Royal Air Force.

Certain accountant officers, Royal Navy.

Officers under instruction, other than those holding commissions or appointments in the Royal Flying Corps.

BLUE UNIFORM TO BE USED

For the period of the war khaki will be worn as service dress; after the war uniform of the same pattern, but of light blue cloth, will be substituted as early as possible. The blue uniform (but this is optional) can be worn by officers during the war as mess kit. The new uniform will not be made compulsory until sufficient time has elapsed for existing uniforms of the R. N. A. S. and R. F. C. to be worn out,

THE USE OF JIGS, FIXTURES, GAUGES AND TOOLS IN AEROPLANE MANUFACTURE

(*Continued from page* 418)

Drilling Jigs

Much greater accuracy could be secured by making the guide bushes for the drills of proper length, relative to the size of the drill. At present many drilling jigs do little more than serve to indicate the position of the holes—there is insufficient bearing to take care of the truth of the drilling.

Limits

As in the case of metal working, absolute accuracy in woodworking is not only impossible, but also unnecessary. Hence, maximum and minimum limits are required for all dimensions in aeroplane work. These limits are naturally much wider than those essential for metal work. For both holes they are usually of the order of plus or minus 0.01 inch. For lengths of under three feet the allowance is normally plus or minus 0.03 inch; for longer pieces the allowance is increased 0.01 per foot; due discretion being exercised according to the circumstances, *e.g.*, on aileron hinge joints of, say, eight feet or so, it would not be more than 0.04 to 0.05 inch, with present day designs. However, hinge design is a matter that should receive more attention. There is a tendency for spars to warp across the grain if exposed to bad weather conditions, hence a limit of 0.05 inch is usually provided to counteract these atmospheric effects.

When seasoned wood has been milled it should be laid aside for about ten days and then drilled by jig before the fittings are assembled. It will then be found that no trouble will be experienced when the parts are fitted together, as there will be no appreciable shrinkage under these conditions.

Board Jigs

Small pieces are generally put together to form components on a board jig. This consists of a board on which small positioned pieces of wood (or in some cases metal) and locking turn buttons are fixed in such a way that a piece of wood placed round the outside or inside will assume the required curve. If these boards were built up on some sort of box frame, or series of small boxes, and the ordinate length stops fixed to sliding pieces, these boards could be turned out in quantities and merely adjusted to the various ribs. This would save considerable time in setting up the board and when a particular rib was finished the board would not be scrap, but could be readjusted to fresh parts.

In the case of board jigs for holding pieces together when glued, the curve must be cut from a board so as to give contact along the whole outside member. Clamping cams, or turn buttons, for board jigs, should be standardized and turned out in quantities so that they can be supplied from stock. These cams should be designed so that they will give a grip that is not too sudden. One of the best designs is that of an eccentric "comma."

Unit Assembly Jigs

The wings, tail planes, etc., should be fitted together in a jig, so designed, that both sides can be worked on and in such a way that it is impossible to assemble a portion in the wrong manner. For glueing operations a number of similar jigs are often required, so that sufficient time may be allowed for the glue to set, without holding up the workpeople. Glued portions should be clamped together until set. On large assembly jigs the design of suitable clamping devices affords exercise for much ingenuity.

A matter that is often overlooked in aeroplane erection is the necessity for cramping together, under considerable pressure, all members which have been cut across the grain in the process of manufacture. The reason for this is, that however well set the saw may be, it always leaves a soft fibrous mass at the end of a piece of wood when cross cutting it. Heavy pressure will bed the ends of sawn members together. In the case of aeroplanes, which are assembled without proper cramping arrangements, it is found that all the tie wires become slack after one or two landings. This is undoubtedly due to the giving of the unbedded ends of the various members.

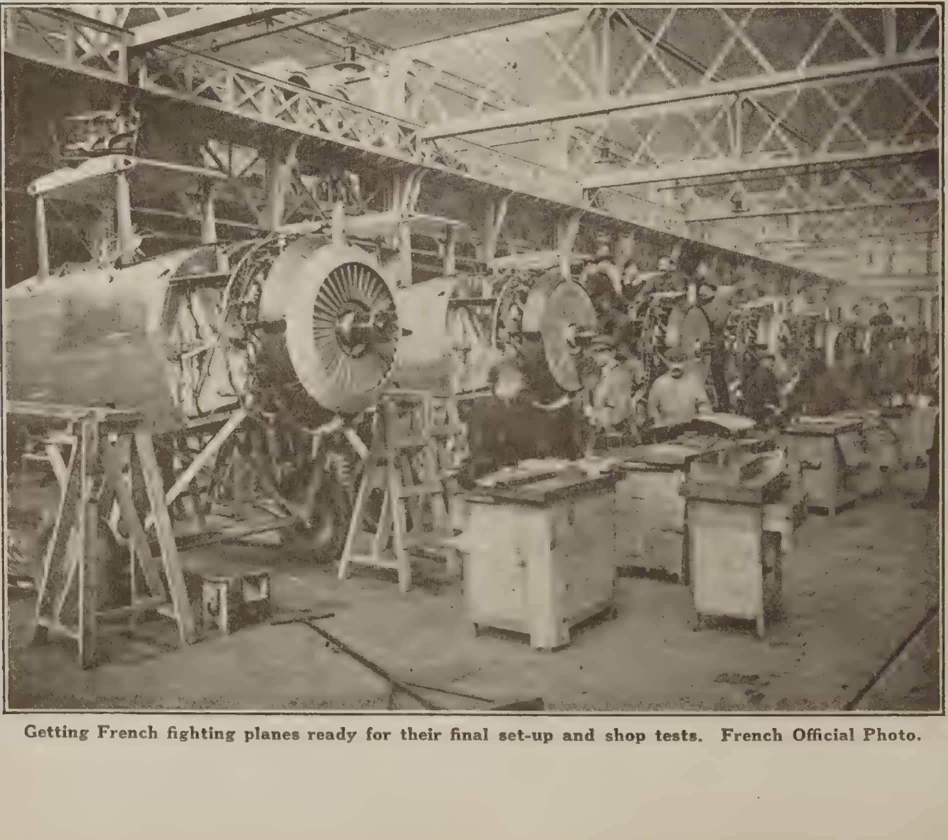
Jigs should be so designed, as a rule, that no operation on them will require more than say two hours' work at a time. Such an arrangement greatly facilitates the passage of work through the shops.

A fixture is in use in several works in which the wings are placed with the correct incidence and dihedral angles. The wires are then strained so that the leading edge assumes such a position relative to a fixed point on the jig that the wing takes up its correct form. The wings are then sent for covering and doping, and it is found that they very seldom require any adjustment when fitting to fuselage. This of course means that wings can be made in quantities and stored, to be withdrawn as required, whether as spares or for fitting to new machines. Some such jigs should be used in the final erection of wings on a machine to ensure that they take up their correct position. To speed up the work a tautness meter may well be used for rapidly testing the straining of the wires.

In one type of fixture, the rear portion of the fuselage is fixed on a sliding table, to have the rudder post fitted dead square and central. There are also guides so that the four front ends of the longerons may be cut off square relatively to the rudder post and to the correct length. The rear portion is then a complete unit, ready to be fixed to the rest of the machine without any further fitting. This is a most desirable fixture and should be used whenever applicable. In the case of large machines the sliding tables should be on the floor level so as to make the job easily accessible.

Erection Fixtures

The whole machine (not necessarily always including the wings and chassis) should be finally erected in a specially constructed fixture. This usually consists of a large surface plate or a concrete



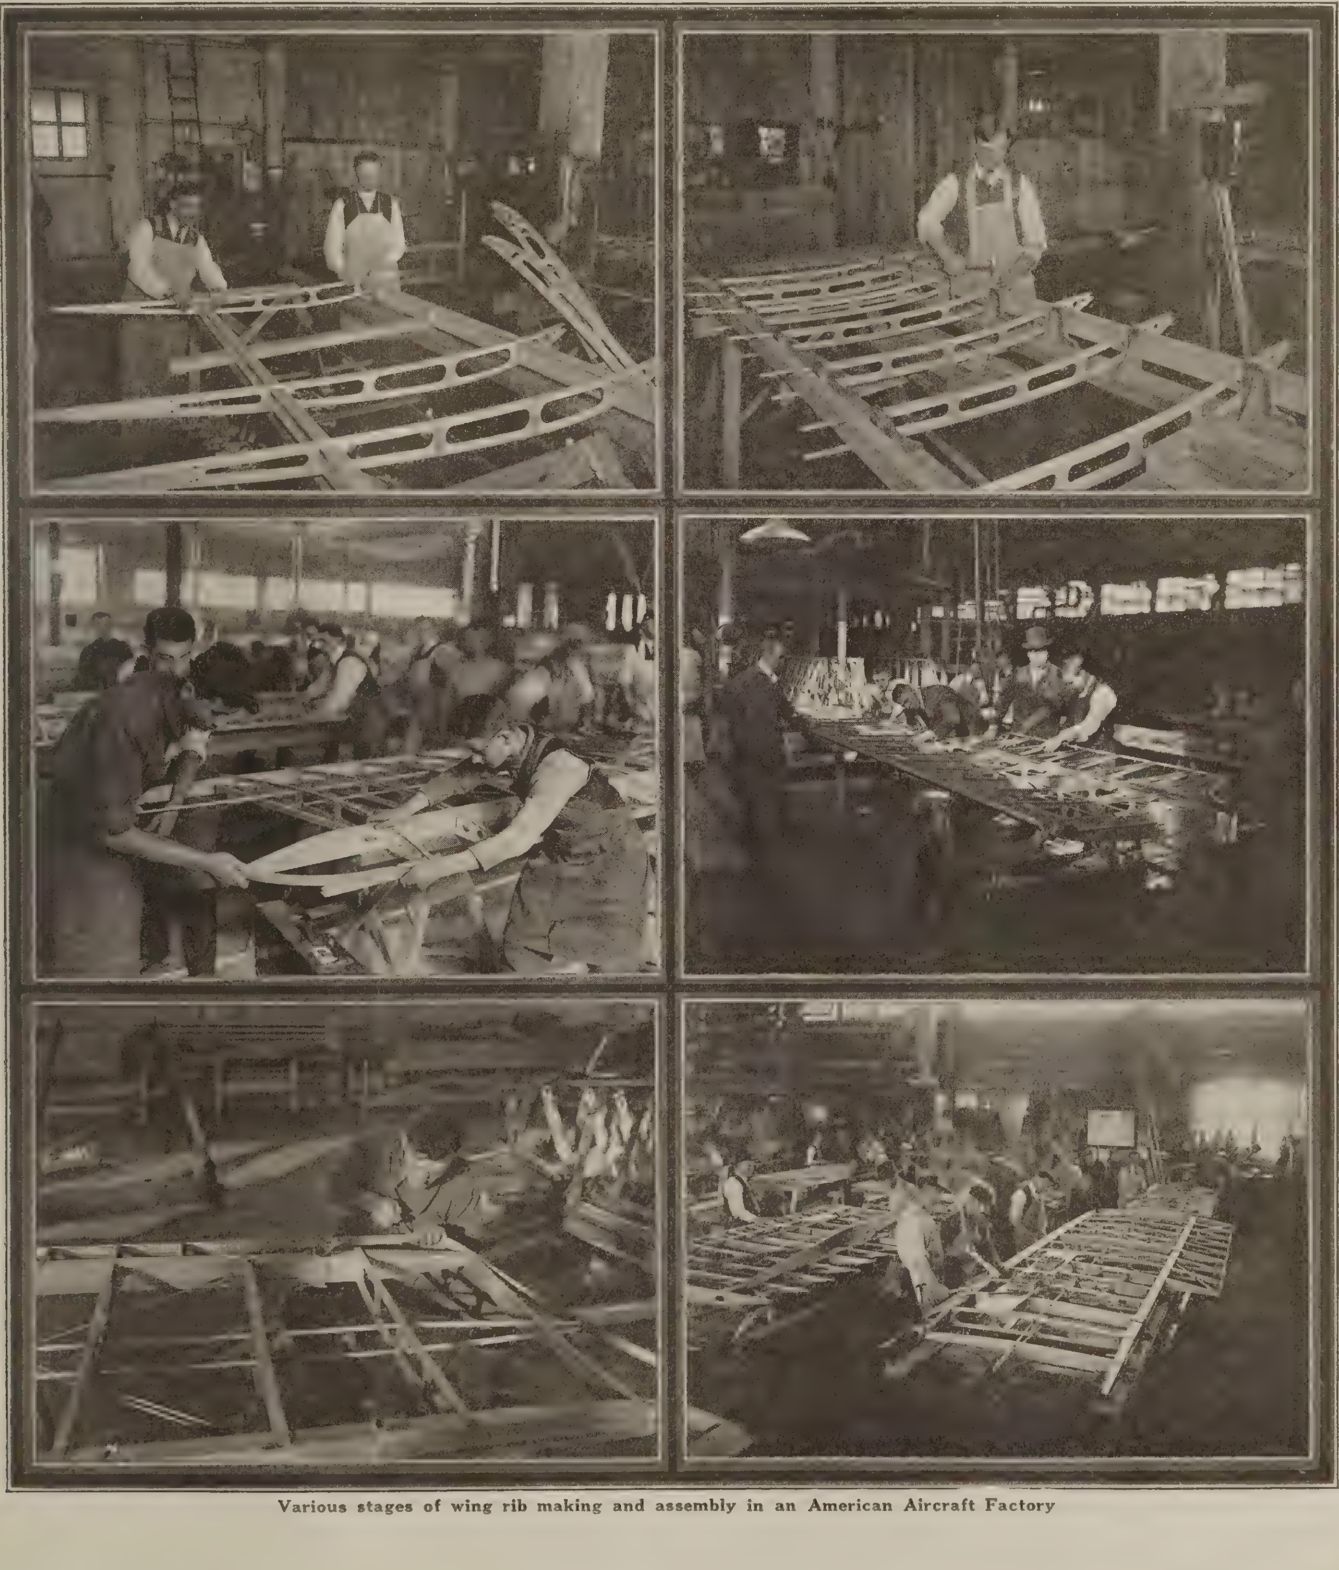
Getting French fighting planes ready for their final set-up and shop tests. French Official Photo.

foundation, with brackets fixed so that the various units must come into their correct relative positions. Less reliable forms consist of timber structures.

In Conclusion

There seems to be no doubt but that for even the building of a small number of aeroplanes, considerable use should be made of both part and component jigs. If the number is in the neighborhood of 50 or so, the utilization of quite a number of unit jigs will be advisable, while for anything over 250 machines, jigging can be carried to a considerable extent with great advantage, including more or less elaborate erection fixtures. In fact the only risk in thorough jigging may be said to be in the case of erection fixtures, owing to changes in aeroplane design. However, even these appliances can be designed upon an adjustable basis.

Reference has been made earlier in this paper to the need of organized design along modern scientific lines. Such methods benefit the worker in enabling him to earn higher wages with less strain, while at the same time it is advantageous to the employer. In this consideration a third great party had been overlooked—the whole nation—the consumers, who purchase the product of the first two, and who ultimately pay both the wages of the workpeople and the profit of the employers. A brief scrutiny of industrial history indicates that finally the whole nation gets the greater portion of the benefit coming from industrial improvement. To this end, therefore, any progress in the development and application that may be made in this connection, must be to the ultimate benefit of the people as a whole—even if it appear to be but a side line in industrial work. At the present moment economy in man



Various stages of wing rib making and assembly in an American Aircraft Factory

Putting the final touches to a French fighting plane. Women are doing very important work in this connection in England and France

accelerate the output of such important war material as aeroplanes should be given very careful consideration, even if it involves such a disturbing effort as the direction of thought along unaccustomed lines.

Such then is the case for the more extended application of the use of jigs and fixtures in the manufacture of aeroplanes.

Expressions of Opinion

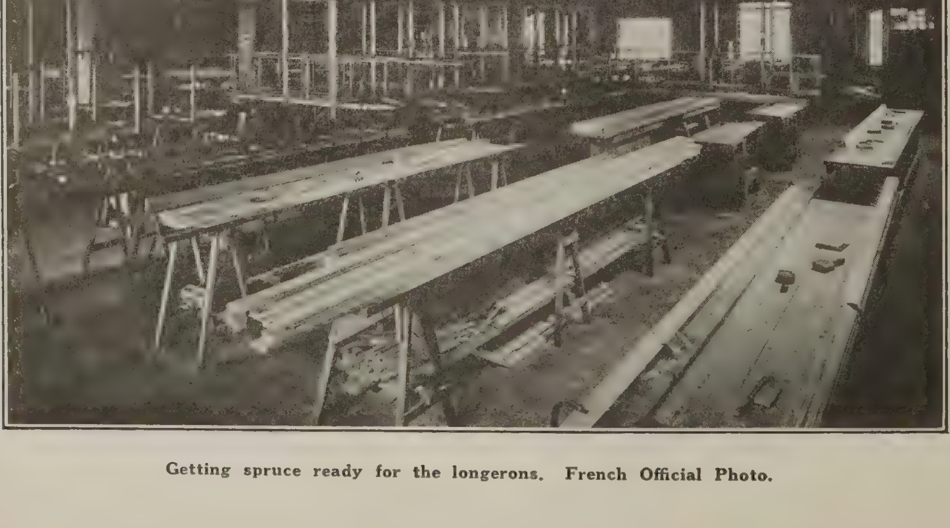
Lieutenant-Colonel Sir Henry Fowler, K.B.E., Assistant Director General of Aircraft Production to the Ministry of Munitions, occupied the chair.

Lieutenant A. R. Low, R. N. V. R., who opened the discussion, by permission of the Superintendent of the Drawing Office, he showed slides depicting the processes of seaplane boat building by the aid of jigs.

Mr. H. R. Hollis showed a slide giving an idea of the method of final erection. This had been slightly accentuated in the United States by the adoption of so-called erection jacks, which made the final erection much easier and obviated the use of plumb lines and temporarily rigged means of locating the various points. The erection jig illustrated had been used with much success by the Curtiss Company and had reduced labor by some fifty man-hours per machine, and so increased the output. These jigs accelerated the production of aeroplanes by 75 per cent, and the straining of landing and flying wires had been reduced more to a science than hitherto by the use of tension gauges. He thought the system shown might with advantage be adopted by more manufacturers in this country. The particular jig illustrated was made from gas piping, and called for no great accuracy, because the trays which carried the wings were adjustable. The total cost of the jig was about something under £100. Its U. S. number was Curtiss DX. The saving of labor on one machine more than paid for its share of the cost of the whole jig.

Captain Outram, R. F. C., said, as an inspector, he supposed he would be expected to be prejudiced in favor of the most elaborate jigging possible, because most certainly the more jigging that was done, the easier the inspector's job. The jigs made in different works on much the same lines differed considerably in detail construction, and often in dimensions, and did not take into account the fact that certain tolerances had to be allowed on the detailed parts. That was an argument in favor of Mr. Borlase Matthews's proposal that drawings of these jigs should be considered as carefully as the drawings of the parts. The jigs being designed with various clamps, there was a great tendency to spring the parts into place and the finished part had sometimes lost truth owing to that.

With regard to the necessity for the checking of jigs, jigs were frequently made of soft wood, and the result was a considerable amount of wear and of moving and warping of the jig, and they required constant checking to maintain them in truth. In one case he could not understand why certain ribs came out different from the drawings, and he found that a man had made a part wrongly and another workman had altered the jig to suit the wrong part. There seemed to be an impression that if a complete component were made in a jig it would be correct in its finished state. That was a fallacy. If a wing were got correctly out of the jig, and covered badly, with too big a strain on it, it was pulled out of truth at once. One had to be very careful, therefore, in deciding at what stage to jig and in watching the effect. He had known elaborate jigs to be made which did not locate the important points of the component. A case occurred recently where with an accurate jig for the fuselage, no attempt was made to locate the fittings for attaching the wings. The fuselage was true, but the wings were out of truth. That pointed to Mr. Borlase Matthews's proposal that the jigs should be carefully designed by a special drawing office. In the majority of cases jigs had to be made up, and one could sometimes make the part he required more quickly than



Getting spruce ready for the longerons. French Official Photo.

he could obtain certain material for the jig. In the design of jigs he thought only the essential parts should be shown, the details being left to the man who made the jig.

Lieutenant Mann, R. F. C., said the main difficulty they had encountered in checking jigs of a large size was the shortage of accurate measuring appliances. They had experimented with steel rules and tapes, but found them unsatisfactory for gauge and jig making. They set to work to get out a cheap form of gauge, so that they could be loaned to contractors to check their workshop gauges. He showed on the screen the first attempt, which consisted of piano wire stretched from end to end of a frame with discs sweated into position upon the wires. He next showed the present form of gauge, which consisted of a timber frame of cruciform section having sheet metal ends, between which the gauging wire was strained. This frame would carry any one of the gauges, the total of which formed the set for the machine. The wire was ¼ in. diameter high tensile steel, and the discs were made on a capstan lathe and faced up in a precision lathe, and were slipped on to the wire and sweated up into position. He next showed an appliance they were adopting for assisting in eliminating the complete erection of machines. Doing away with any work increased production, and by avoiding the erection of wings they saved floor space which could be used for other purposes. There had been a lot of difference of opinion as to limits and what clearances were necessary. He showed a table giving information in regard to these matters, and to hinges used in various components.

A French reconnaissance machine being tuned up before leaving the factory for field tests.

Captain S. W. Hiscocks, R.F.C., said if a machine had to be turned out in a week it was impossible to make all the parts to jig. The fault in some of the jigs that had been shown seemed to be due to the original design of the machines. The jigs seemed too elaborate considering the cost of the parts involved. His experience was that the majority of those who had gone into the aeroplane designing business had not the faintest idea how the parts were made or assembled, though there were a few exceptions. There was no need to have a machine for making struts. It could be done on an ordinary spindle.

He would say further that the question of the number of jigs that could be made for production purposes did not depend so much on the production side as upon the people who were responsible for getting out the designs and placing orders for machines.

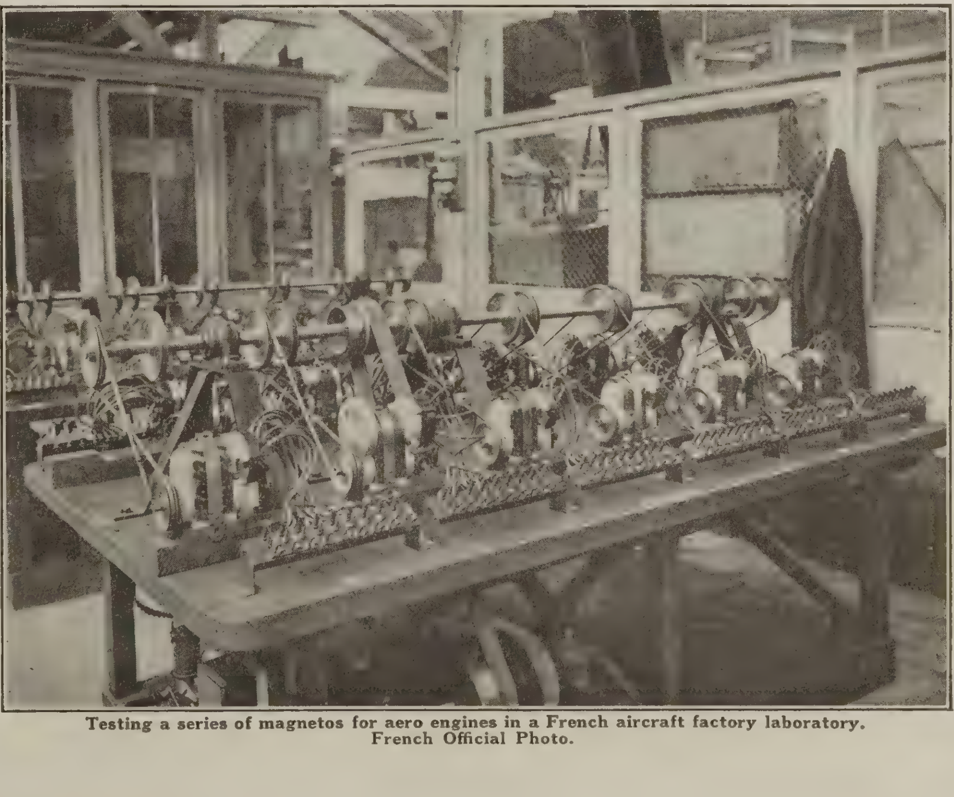
In many cases the manufacturers are asked to start delivering machines before the drawings are completed, and to do this a large number of parts have to be made by hand from rough sketches, so as to get the production going during the time required to make the necessary tools and jigs for producing parts.

If the country wants cheap production of aeroplanes, it will be necessary to allow some two or three months between the completion of the design and the delivery of the first aeroplane to that design, to enable the manufacturers to lay the work out properly.

Another difficulty in connection with arranging for the use of jigs is that the design of a number of the parts is such that cheap production and assembly by use of simple jigs is impossible, especially so as many of the drawings do not include the necessary limits to ensure interchangeability.

This, he thought, was due to the fact that the aeronautical industry, from a manufacturing point of view, was only about three years old, and that the draughtsmen who prepared the drawings had not had shop experience in the manufacture of aeroplanes.

As an example of the above, one of the photographs shown by the lecturer illustrated a strut copying lathe, which to his mind was an unnecessary machine, as it was quite easy to design struts so that they could be finished, with the exception of cutting to length, direct from the ordinary common spindle, thus cutting out the use of an expensive machine and saving time in production.



Testing a series of magnetos for aero engines in a French aircraft factory laboratory. French Official Photo.

An interesting type of aircraft factory building. The "jobbing" room in a French factory, where work of a general nature is done. French Official Photo.

Mr. H. Pearman said it was the same now as in the early motor car days as regarded the deplorable difference in the amount a firm would spend on plant and that which they would spend on so-called non-productive equipment, and the result was inefficient production. The lecturer's suggestion with regard to the centralization of jig and tool fixture design was a good one, particularly in view of the control manufacturers were now under. Manufacturers would appreciate the establishing of the principles of the design in a central office, and they would be broad-minded enough to accept such designs in a proper spirit, and greater efficiency would result. A person spending £500 on a machine should be willing to spend £20 on equipment.

Mr. F. Handley Page said he thought the Services required a little tuition, and not the manufacturers only. There could not be standardization of production unless there were unity of demand. Large numbers of machines could not be turned out if changes were made every week. There was a great difference between manufacturing for a Service and manufacturing for a public. In the latter case the public could be persuaded that they wanted what one had to offer, and then thousands or hundreds of thousands of the article could be produced, but it was difficult to persuade a Service, who interrupted the manufacturer frequently with fresh modifications. It was therefore to the Service side that an appeal for unity of demand had to be made. Mr. Borlase Matthews said there were very few jig and tool drawings in this country. He thought the country was hardly so uncivilized as that would indicate. He thought in all decent works there were as many jig and tool drawing offices as ordinary drawing offices. In the case of larger machines than those shown on the slides the question of dividing the machine into units which could be easily assembled separately was of vital importance. It was impossible to have a machine with 100 ft. planes completely erected. In the case of his works the planes and other large parts were assembled separately from the machine. He would like to ask Mr. Borlase Matthews whether it was practicable to erect all one's planes in a vertical position, instead of the horizontal method of assembly? Had any manufacturers experience of assembling planes in this way?

Captain Bishop, R.F.C., said he agreed that the drawings of jigs and fixtures should have more time devoted to them than they had. He remembered one case where contractors complained that the tolerances were too small. New drawings were got out giving exceptionally large tolerances. The contractors then complained that they were too large, as parts made to them would not fit their jigs. Where jigs were instituted higher precision work had to be instituted in the preceding operations. With a long run of production erection jigs were worth making, but his people once laid out a jig on those lines, and by the time the jig materialized the aeroplane was finished. Most gauges required a certain tolerance, and that, as well as the tolerance for the parts, should be allowed for in dimensioning up the various machines.

Mr. Davidson said if jigs were designed at the time the machine was being aero-dynamically considered it would be easier for the manufacturer, as alterations and modifications would not come through in the present quantities, and they would be checked when the jigs were being got out. The limits of interchangeability would have to be considered also, so that several matters could be settled at one time. If there were a central office for designing jigs, and the best way of making a certain part were discovered, that way would be standardized and everybody would not have to make experiments.

Mr. Pettit said a vital matter to consider was the getting of a big output of machines. Mr. Matthews was rather unfortunate in the choice of one slide which showed a fuselage building jig, and in which the longerons were located by blocks placed inside the longerons and the cramping devices came on the outside, the result being that the compression would be up against the wood block rather than

THE ALBATROS TYPE "CV" FIGHTER

(*Continued from page 261*)

THE cockpits of the Albatros are arranged in the fashion now universally adopted for two seaters, by Allies as well as by the enemy, i.e., the pilot in front and the gunner in the rear cockpit. The pilot's seat is mounted, in the Albatros, on the main fuel tank, which has two annexes on top, one on each side of the seat. This arrangement is clearly indicated in Fig. 12, in which the small clips preventing the seat from sliding about on the tank will be noticed. The filler cap is mounted on a tubular projection extending through the fuselage covering, thus enabling the tank to be refilled from the outside. A smaller auxiliary tank is mounted above and to the rear of the main tank, in the gunner's cockpit, as a matter of fact. Both tanks are connected up to a by-pass or distributor, so that both or either tank can be connected up to the engine, two pumps being provided for maintaining the necessary pressure, one driven by the engine and the other hand operated. Thus, whatever tank is being used, petrol is fed to the carburetor under pressure. This has probably been a necessary provision, as the tanks are placed relatively low and gravity feed would, therefore, be apt to be unreliable when the machine is climbing at a fairly steep angle.

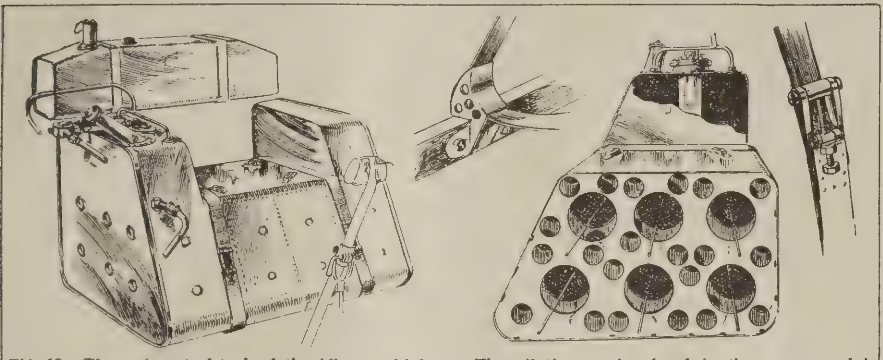

Fig. 12.—The main petrol tank of the Albatros biplane. The pilot's seat is placed in the recess, and is prevented from sliding about by the steel clips shown. On the right is shown a section of the tank, with the internal bracing rods and baffle plates. The insets show the brackets supporting the tank, and the arrangement for tightening the straps that hold the tank.

Constructionally the petrol tanks are of interest in that they have been internally braced by rods running across from side to side, the attachment of the rods being visible on the outside of the tank as shown in Fig. 12. To prevent the petrol from slushing about inside when the tank is nearly empty baffle plates are fitted dividing the main tank longitudinally into five compartments, communicating with each other through the circular openings shown in the section of the tank, Fig. 12. As the supply pipe leaves the tank fairly high up—it can be seen on the front right-hand side of the tank in Fig. 12—it is carried down inside to the bottom of the tank so as to enable the last drop of petrol to be forced out and into the carburetor. The main tank is mounted on brackets as shown in one of the sketches, and is secured by metal straps having an arrangement for adjustment.

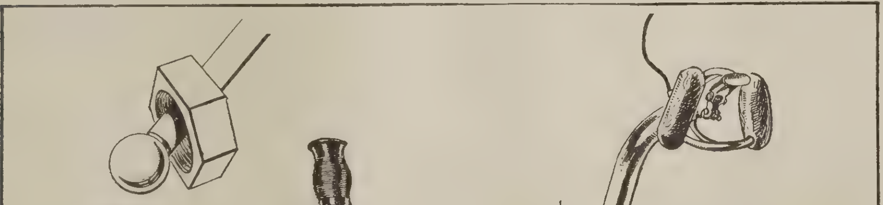

Fig. 13.—The controls of the Albatros biplane. Insets show the ball and socket joint for the control lever locking arrangement, and hand grip with gun trigger on the main control lever.

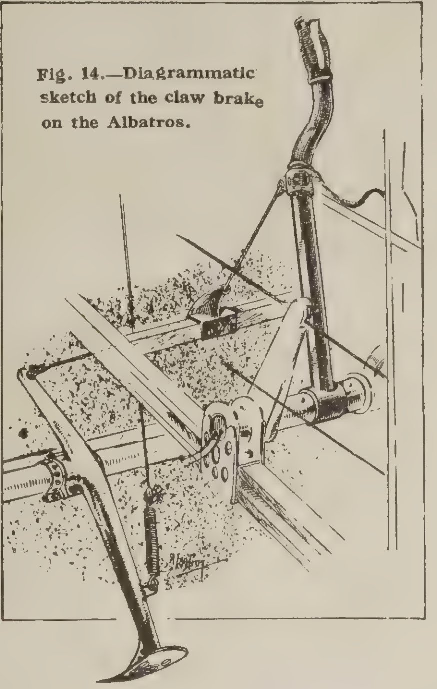

Fig. 14.—Diagrammatic sketch of the claw brake on the Albatros.

In Fig. 13 is shown the general arrangement of the controls. There is a transverse rocking shaft of which are mounted at each end crank levers for operating the elevators, while in the centre, pivoted so as to be free to rock laterally, is mounted the main control lever. Mounted on the transverse shaft, but not moving with it, is another lever, which operates the claw brake mounted on the wheel axle. The arrangement of this brake is shown in Fig. 14. By pulling the lever the free end of the claw brake is pulling upwards, thus causing the claw to dig into the ground. On releasing the lever, the brake is returned to its normal position by the action of the spring shown in the sketch.

The transverse rocking shaft is carried, as indicated in Fig. 14, in two bearings mounted on the lower longerons. A forward and backward movement of the control lever causes the shaft to oscillate, and with it the two crank levers to which are attached the elevator control cable. These cables run from the crank lever, around a pulley slightly forward of the transverse shaft as shown in the sketch, and hence to the top crank lever on the elevator. The return cable runs from the crank on the under side of the elevator to the crank on the transverse shaft. En route these cables pass over pulleys mounted in the rear position of the fuselage, these pulleys being shown in detail in some of the accompanying sketches (Fig. 15).

As regards lateral control, the general arrangement of this is indicated in diagrammatic form in Fig. 16. From the control lever the direct cable passes over a pulley on the transverse shaft, along through the bottom wing, around another pulley in the wing, and hence to the rear half of the aileron crank lever. The return cable runs from the front half of the aileron crank lever, around another pulley in the lower wing, through the wing and through the transverse shaft to a pulley on the other side of the control lever, and hence to the screw on the control lever. The details will be clear from Fig. 13.

The foot bar operating the rudder is mounted on a pyramid of steel tubes, and the rudder cables are taken, not, it will be seen, from the foot bar itself as is generally done, but from a short lever projecting forward at right angles to the foot bar. From this lever the cables pass over pulleys and to the cranks on the rudder. It will be seen that provision has been made for making adjustments of the foot bar to suit pilots of different height by fitting on extra foot bar. If the machine is to be flown by a taller pilot, this is removed and the main foot bar used. Wire clips are provided, it will be noticed, for accommodating the pilot's heels so as to prevent his feet from slipping off the foot bar.

As in the majority of German machines, provision has been made for locking the control lever in any position, either flying level, climbing, or descending. This is accomplished by means of a collar free to slide along the control column, but being split and provided with a bolt for tightening up, when the collar is locked in position on the control column. Anchored to this collar by two screws is a fork end, from which

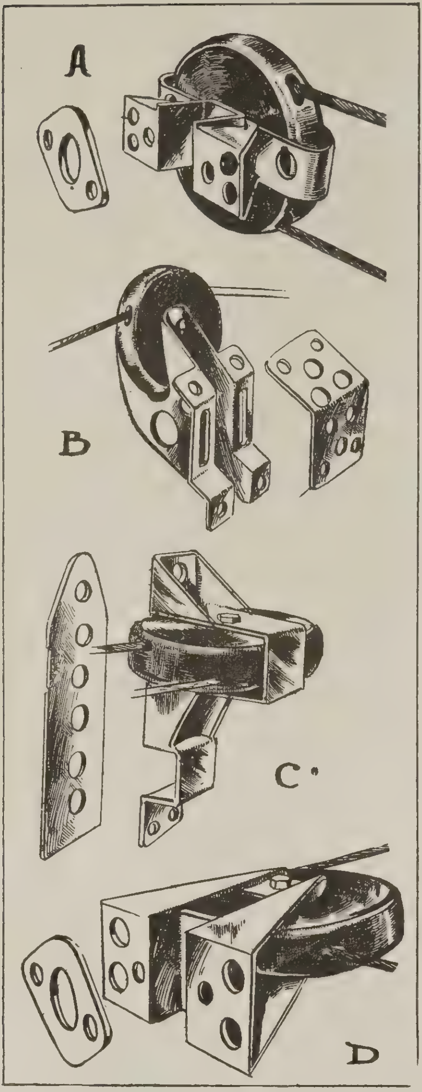

Fig. 15. "A" shows the pulley over which the elevator cable passes after leaving crank lever on rocking shaft (See Fig. 13). "B" the pully mounted on the top longeron (in front of the tail plane) over which the elevator control passes. "C" This pulley bolted to the middle longeron just ahead of the tail plane guides the elevator cable. "D" This pulley guides the rudder cable in front of the footbar.

a tube runs down and forward to terminate in a ball and socket joint secured to the bottom of the fuselage. This ball and socket joint, it will be seen, enables the control column to be moved freely in any direction, and to allow it to be moved from side to side, even when the forward movement of the column is prevented by locking the collar. In this manner, the pilot can lock the elevator, while operating the control column from side to side for lateral control with his knees.

As far as can be ascertained, although the machine gun was not in place on the machine as exhibited, one synchronized machine gun was fitted, resting on top of the fuselage on the right-hand side. The pilot operated this gun by means of the trigger on the hand-grip of his control lever, which is shown inset in Fig. 13.

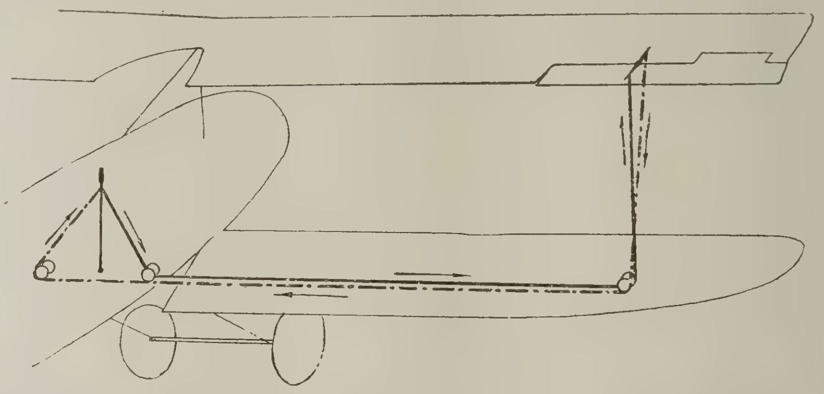

Fig. 16. Diagram of the aileron control system of the Albatros Fighter

While on the subject of controls, reference might be made to the crank levers on the elevator and rudder. These are shown in Fig. 17, from which their construction will be evident. The crank lever of the elevator has projecting from it a tapering tube running to the trailing edge of the elevator. The tubular rudder post is working in bearings similar to those described in our last issue when dealing with the hinges for the elevator. At the bottom the rudder tube fits into and is supported by a socket carried on a clip bolted to one of the transverse bulkheads of the fuselage. A peculiarity characteristic of the Albatross is the method of attaching the control cables to the crank levers. A socket is formed in the end of the crank lever, and into this fits a cup-shaped piece of steel machined on one of the bolts of the wire strainers, much in the same manner as the terminal attachment of the main lift cables. Thus any vibration in the control cable is not transmitted to the crank lever, the cup-shaped head of the turn-buckle bolt being free to move in its socket in the crank lever.

Reference has already been made to one part of the armanent of the Albatros, namely, the synchronized machine gun operated by the pilot from the trigger on the main control column. In addition there is a movable machine gun mounted on the usual gun ring in the rear cockpit. The general arrangement of this gun mounting is shown in the sketch, Fig. 18. The gun ring itself is built up of thin three-ply wood, and runs on small rollers on its support so as to reduce friction. It is prevented from tilting up by wooden angle pieces screwed to its underside and overlapping the fixed support. The whole arrangement looks somewhat clumsy, but is apparently quite light, and the strength is probably reasonably good, as the three-ply of which the gun ring is made is made up of different curvatures, each of which tends to strengthen the others.

The machine gun is supported on the gun ring by a swivelling fork, which can be raised and lowered as required, and which can be locked in any desired position by the locking arrangement indicated in the sketch of the general arrangement. In addition to its circular movement integrally with the gun ring, the machine gun may be swung laterally on its pivot in the gun ring. Here also a locking device is provided in the shape of a split collar locked by an L bolt, as shown in one of the insets. The other inset in Fig. 18 shows the lever by means of which the gun ring is locked in any desired position. A rocker arm composed of two steel strips is pivoted in its center on a pillar projecting downwards from the gun ring. At one end this rocker arm carries a plate welded to the two steel strips of the rocker, and at the other it carries the hand lever which is so formed and pivoted as to give an eccentric movement when the lever is swung through an arc. The *modus operandi* will be clear from the sketch. When the gun ring has been swung around to the desired position the hand lever is pushed down; in so doing the eccentric forces the inner end of the rocker down, thus causing its outer end carrying the flat plate to move up against the fixed support for the gun ring and thereby locking it. A pull on the lever instantly releases the gun ring if it is desired to swing the gun around to another quarter.

As presumably it frequently happens that the gunner wishes to fire from a standing position his seat has been so arranged as to swing into a vertical position as soon as it is relieved of its weight. This is accomplished by means of a spring under the seat, as shown in Fig. 19, which is, we think, self-explanatory. A strip of

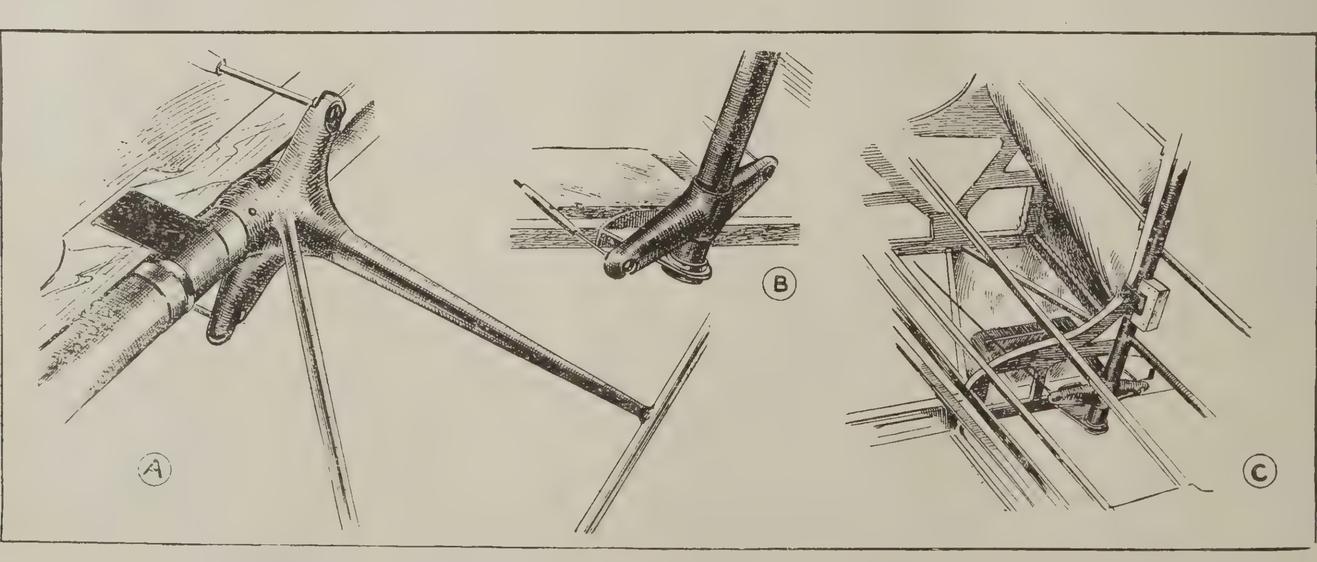

Fig. 17. Elevator and rudder crank levers on the Albatros biplane. (A) Elevator crank lever with its ball socket joint for the turnbuckle. (B) Bottom rudder bracket and crank lever. (C) Mounting of the rudder.

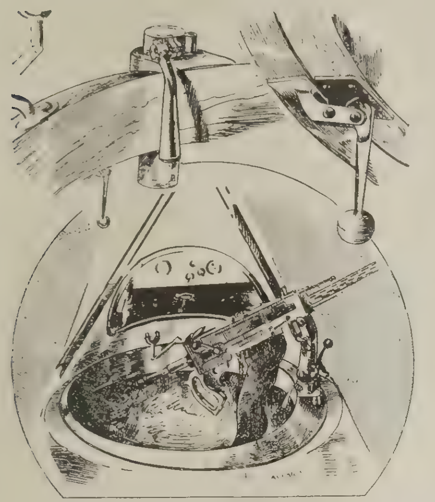

Fig. 18. The machine gun and its mounting on the Albatros Fighter. The bag for the spent cartridges should be noted. When not in use, the butt of the gun rests in the clip shown. The two smaller sketches show the locking devices for the gun pivot (left) and the gun ring (right)

wood runs transversely under the seat and projects a short distance on either side. These projections rest, when the seat is in a horizontal position, in brackets secured to the sides of the fuselage.

The Albatros biplane belongs to the C class, that is to say, is a general utility machine variously used for fighting, reconnaissance, artillery spotting and photography, and is therefore not to be considered a bombing machine. It is, however, provided with racks for a small number of bombs—four, to be exact—presumably by way of cases of emergency when a suitable target might present itself. Fig. 20 is a diagrammatic perspective view of the bomb racks and bomb release gear. The bombs are secured underneath the main tank in the pilot's cockpit, but they are released by the gunner in the rear cockpit by means of a small lever and quadrant shown in Fig. 20.

The bomb racks are in the form of sheet steel supports, against the bottom of which rest the nose and the tail of the bombs respectively. These brackets are secured to transverse members in the bottom of the fuselage, which have been omitted in the drawing for the sake of clearness. The bombs themselves are supported by a steel strap or band, passing underneath and approximately under the middle of the bombs. At one end the straps are hinged, while at the other they are provided with an eye, which is secured in the hook under the release trigger. One of the sketches in Fig. 20 shows in more detail the hook in which the eye of the strap rests, and the trigger by means of which the strap is released. The trigger is pivoted near its centre, and has an upward projection to which is attached a small coil spring resting in a groove in the base supporting the hook. When the cam on the transverse shaft presses down the rear end of the trigger, the front end moves upward against the tension of the coil spring mentioned above, thus releasing the strap and with it the bomb.

As regards the cams which operate the bombs, these are mounted on a transverse shaft running across the bottom of the fuselage. There are four cams, each operating its trigger, but the gearing of the camshaft is such that it requires five pulls on the lever in the gunner's cockpit to rotate the shaft through a complete revolution. One of these pulls of the lever has no corresponding cam on the shaft, and has, it appears, been incorporated in order to provide an equivalent of a safety catch. When all the bombs are in place the first pull on the lever does not release a bomb, but merely brings the cam for bomb No. 1 into position, ready to press, on the next pull of the lever, the trigger for the first bomb. This has evidently been done as a precaution against accidentally releasing a bomb until the machine is approaching an objective.

We now come to consider the method of operating the transverse camshaft. Near the right-hand side of the fuselage there is mounted on the camshaft a small ratchet having five teeth, as shown in Fig. 20. On this ratchet is a small cam, roughly of cone shape. This cam engages with grooves in the pulley around which passes the operating cable. A small leaf spring engages at the proper moment with the notches in the ratchet and prevents the shaft from rotating in the reverse direction. One end of the operating cable is attached to a coil spring secured to the side of the fuselage, and passes from there around the pulley to the lever in the gunner's cockpit. Assuming that the first cam is in position ready to release its bomb, a backward pull of the lever rotates the pulley and with it the ratchet and camshaft, thus pressing down the trigger of one of the bomb racks and releasing a bomb. When the gunner releases the lever this is pulled forward to its normal position by the spring on the side of the fuselage. The little leaf spring engaging with the ratchet prevents this and the shaft from following the pulley round in the opposite direction, and the cam on the ratchet sliding up the sloping bottom of one of the five grooves in the face of the pulley forces the pulley away from the ratchet against the compression of a small coil spring shown in the sketch. By the time the lever has reached its forward position, the pulley has revolved to such an extent as to bring the cam on the ratchet into the next groove in the pulley, and when the lever is again pulled the whole action is repeated. The sketch will probably help to make the action clear.

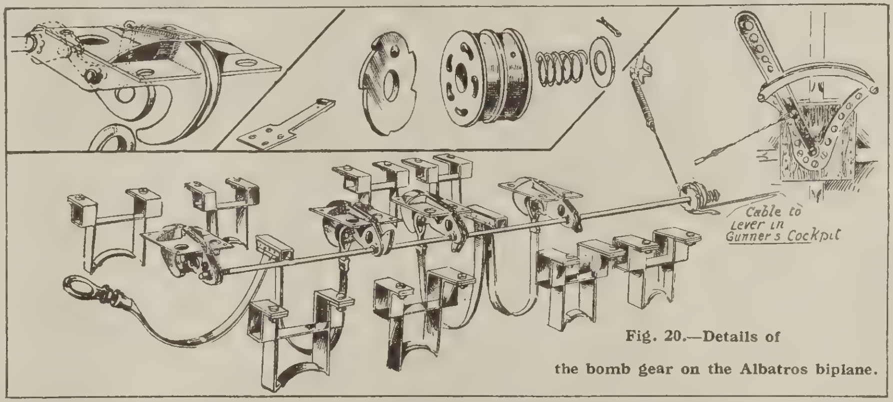

Fig. 20.—Details of the bomb gear on the Albatros biplane.

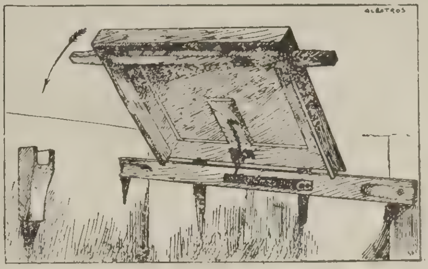

Fig. 19. So as to be out of the way when the gunner is firing from a standing position, the seat on the Albatros Fighter is hinged and sprung as shown in this sketch

In addition to a bomb release lever, there is in the gunner's cockpit another lever, the function of which appears to have been to engage and disengage a clutch near the engine, by means of which a drum is operated carrying the aerial of the wireless. In the bottom of the gunner's cockpit, near the left-hand side, is an octagonal opening in the floor, in which, so far as we can make out, the camera was mounted. The compass, so as to be visible from both cockpits, has apparently been mounted in a circular opening in the right-hand lower main plane.

We now come to deal with the wings of the Albatros. These are, generally speaking, of the construction favored by the Albatros designer, that is to say, the front spar is well forward close to the leading edge, and the rear spar is approximately half-way along the chord. In addition, there is a third false spar, which is not, however, connected up to the body nor supported by any struts, and which cannot therefore be considered as taking any particularly important part of the load. It will, therefore, be realized that the rear main spar may at small angles of incidence, when the centre of pressure moves backwards, be called upon to support all or nearly all of the load. This has evidently been guarded against in the Albatros by making the rear spar of generous proportions. Both main spars are made of spruce, and are of the box type, consisting of two halves spindled out and glued together with a hardwood tongue running through both flanges. The ribs are of I-section, with spruce webs and ash flanges. Between the main spars false ribs are employed half-way between the adjoining main ribs, so as to better

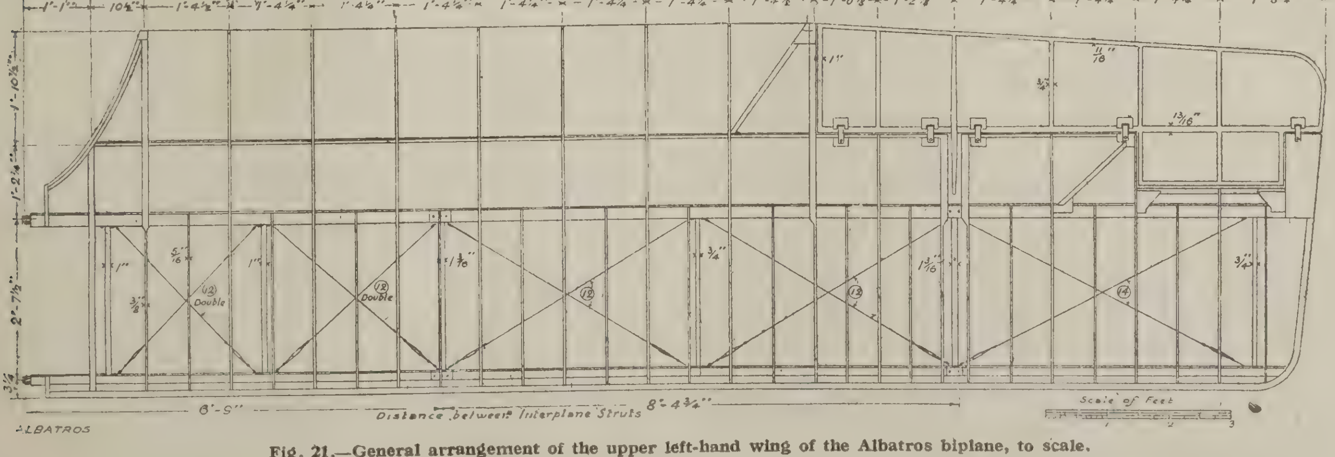

Fig. 21.—General arrangement of the upper left-hand wing of the Albatros biplane, to scale.

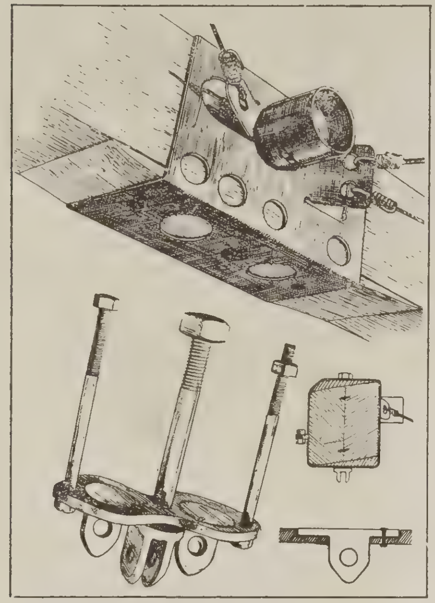

Fig. 22. Sheet steel spar box and socket for compression tube of the upper plane of the Albatros biplane. The bottom sketch shows the attachment of the terminals for the interplane cables and struts

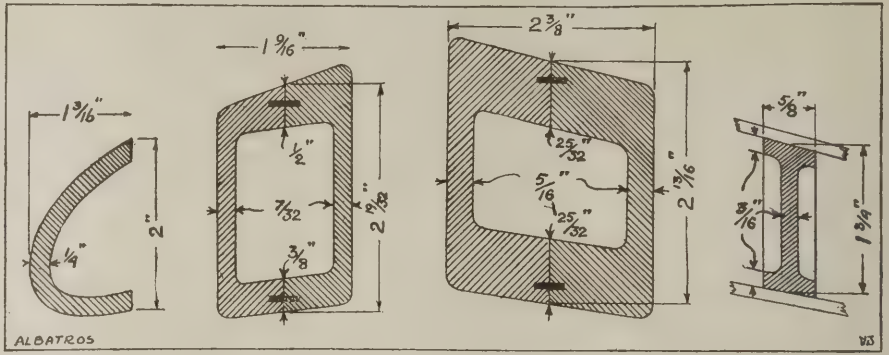

Fig. 23. Sections of the leading edge, main spars and false spar of the Albatros biplane

preserve the curvature of the wing for this distance.

The general arrangement of the upper left-hand wing is shown with dimensions in Fig. 21, from which the general lay-out of the wing will be clear. The internal drift wiring is in the form of five bays, the compression struts for this wiring being in the form of circular section steel tubes. In the two inner bays both drift and anti-drift wires are in duplicate and are approximately 12 S.W.G. The next two bays have single wiring, also of 12 S.W.G., while the outer bay has single wiring of 14 S.W.G

The attachment for the compression tubes and the drift and anti-drift wires is shown in Fig. 22. A box of thin sheet steel surrounds the spar at this point and is bent over and bolted as shown in the small section in Fig. 22. On the inner face of the spar this sheet steel box has two wiring plates stamped out, which receive the drift and anti-drift wires. A short cylindrical distance piece is welded on to the box, and around this fits a short tubular sleeve held in position by a slit pin. This sleeve forms a socket for the tubular compression strut.

Vertically the spar is pierced at this point by three holes, for the bolts securing the interplane strut and the two interplane cables. The attachment for the latter is shown in Fig. 22. The base plate has machined in it two recessed circular openings which receive the two terminals for the cables. These terminals are prevented from rotating by a small rivet as shown in the sectional view. In order to further strengthen the spar at the point where it is pierced by these three bolts, the spar is left solid for a short distance on each side of the box, and packing pieces are interposed between the box and the spar, so as to bring it up to an approximately rectangular section in order to get the bolts coming through the spar and base plate at right angles.

In Fig. 23 are shown sections, to scale, of the two main spars, the false spar, and the leading edge. The trailing edge is, as in the majority of German machines, in the form of a wire.

Fig. 24 shows the shape and dimensions of the wing section. As in nearly all German machines, the camber is, it will be seen, extremely great, both as regards the upper and lower surface.

The precise object of employing such a wing section is not at once apparent, but it should be remembered that the German machines carry a comparatively great load per square foot of wing surface, and the probabilities are that the section has been designed with a view to enable the wing to support this high load at comparatively great altitudes, and has, therefore, probably an excess resistance at lower levels.

This is not quite clear, however, and it would be extremely interesting to have the results of wind tunnel tests on some of these German sections, and we sincerely hope that the National Physical Laboratory may be able to find the time to carry out such experiments.

Superficially the section does not impress one as being particularly efficient, but wind tunnel tests might reveal the fact that it is a good section for carrying high loading at considerable altitudes.

(To be continued)

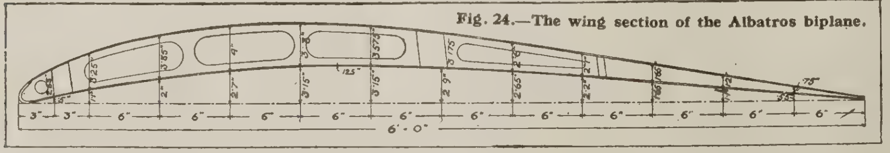

Fig. 24.—The wing section of the Albatros biplane.

(*Continued from page* 437)

of planes." This is another gross fallacy; we cannot really begin the construction of airplanes until our engine and its working horsepower has been established. In other words, except for the acquired material experimentation carried on under various producers and paid for by the cost-plus contract system, enjoyed by manufacturers who are agreeable and acceptable to the ring, we have accomplished nothing in our aeronautic program. Charges could not be more serious. Charges more grievous could not be made against a department or a group of men. Seven or eight investigations have been made besides my own and there is no single, definite denial of anything I charge. Why is it then that this offends? Why is it that placing the truth before the authorities fails for months to meet with response and finally with brusque rebuke, and why after the work is done and delivered a month or more should I receive a letter from you refuting the authority which alone brought me to Washington and under which I have worked so long?

Little can I add to what I have said, and there is little that I wish to add. I am now certain my services have at least compelled some kind of an investigation, and I have at least informed the country of its needs and the camouflage deliberately planned by a group of men entrusted with a great arm of our military machine has come to an end—I hope it has come to an end, but the chart of reconstruction which I saw the day before yesterday fills me with definite alarm.

GUTZON BORGLUM."

Complained Early of Obstruction

The other letter to the President made public by Mr. Borglum follows:

"Washington, D. C., Jan. 21, 1918.

Mr. Dear Mr. President:

I am placing in your hands today a report upon the aeronautic situation, entering as deeply as I have been able to do considering the circumstances.

The statements, grave as they appear, are based upon a mass of information available to you or to any one you may hereafter designate to receive it, except those who have used their official position to delay, mislead, and obstruct the nation's work and my effort to get the truth and so give value to my inquiry.

Before I had been here twenty-four hours I found that my presence and purpose were known; that I was watched; that officials who should have aided me had intercommunicated, attempted to mislead me and block every avenue I approached. I was in a quandary as to what was best to do, resort to the authority of your letter and demand vesture of such authority from the Secretary of War as was necessary to secure data, or to hoe my row alone. I informed the Secretary of War of my difficulties—with the result that I have made my investigation without aid.

Further than this, I have disturbed no one. My own large personal acquaintance stood me in good stead; I gained entrance and secured evidence everywhere, and fortunately have been able to connect the broken links of a chain of dishonesty and disorder that runs throughout our production department. I have seen records, received copies of reports, been the centre of information volunteered from officers, members of Congress, merchants and manufacturers. I have sent agents to the factories, was refused or equally hindered by delay by General Squier, and so what I send here has been wrung from official Washington from men sworn to help, men whose whole lives would be benefitted by frank service in the work they are engaged upon for you and for the nation.

I am speaking in this way because I have only the faintest hope that what I have done will be or can be quickly and constructively applied to our departmental government. What I suggest will require men of courage, fearless prosecution, almost immediate seizure of the manufactories engaged in the work here investigated, without reference to the unhappy men who have crept into regular army officers' uniform and who will get in time a regular army officers' court-martial.

(*Continued on page* 469)

MATHEMATICAL EXPRESSIONS FOR CLIMB, RATE OF CLIMB AND CEILING OF AN AEROPLANE*

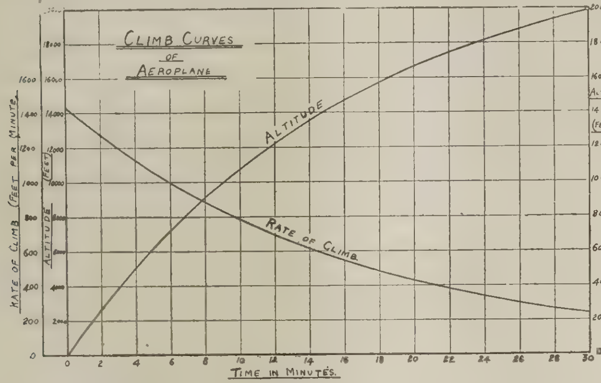
By E. F. C., B.Sc.

THE altitude, at any time, of an aeroplane climbing at its maximum possible rate, is very nearly represented by a mathematical law similar to that for the rise of electric current in an inductive circuit. Thus if h be the altitude at a time, t and H the "ceiling" of the machine, we have the relation

$$h = H\left(1 - e^{-\frac{t}{T}}\right) \qquad (1)$$

where e is the base of the natural or Napierian logarithms and T is a time, which, by analogy with the electrical case, may be called the "time constant" of the climb, being the time required by the altitude to become $1 \ \frac{t}{T}$ or .632 of its final value, *i. e.*, for the aeroplane to rise to a height equal to 0.632 of its ceiling.† Except that h and H and also t and T must be measured in the same units of height and time respectively, there is no restriction in this formula on the units used.

This being the case, it is possible to find expressions for the rate of climb at any time and at any altitude, and also an expression for the ceiling of the machine, which latter is quite simple. We will first show how to obtain such expressions from the equation already given and afterwards will give the application of these to a practical case.



The rate of climb is obtained by differentiating h with respect to t, and is

$$\frac{dh}{dt} = \frac{H}{T} e^{-\frac{t}{T}}, \qquad (2)$$

which is an equation giving the rate of climb in terms of the time, the ceiling, and the time constant.

By eliminating the exponental $e^{-\frac{t}{T}}$ from equations (1) and (2) we obtain an equation giving the rate of climb in terms of the altitude, the ceiling, and the time constant. This equation is

$$\frac{dh}{dt} = \frac{H}{T}\left(1 - \frac{h}{H}\right) = \frac{H - h}{T},$$

and shows that rate of climb plotted against altitude is a straight line. If we call rate of climb r we have

$$rT = H - h$$

or

$$\frac{h}{H} + \frac{r}{H/T} = 1 \qquad (3)$$

which equation shows that when r is plotted against h, the intercept (H) of the straight line on the altitude axis is the ceiling of the machine (where rate of climb $r = o$) and the intercept $\left(\frac{H}{T}\right)$ on the rate of climb axis is the initial rate of climb (*i. e.*, rate of climb when $h = o$).

The simple expression for the ceiling of a machine is obtained as follows:

After any time t from the start let the observed altitude of the aeroplane be h_1, and after a time $2t$ let it be h_2. Then we have

$$h_1 = H\left(1 - e^{-\frac{t}{T}}\right)$$

$$h_2 = H\left(1 - e^{-\frac{2t}{T}}\right)$$

Let us write X for the exponential $e^{-\frac{t}{T}}$ for convenience, then:—

$$h_1 = H(1 - X)$$
$$h_2 = H(1 - X^2)$$

whence by division $\frac{h_2}{h_1} = 1 + X$

but since $\frac{h_1}{H} = 1 - X$

$$\therefore \frac{h_1}{H} = 2 - \frac{h_2}{h_1}$$

and

$$H = \frac{h_1}{2 - \frac{h_2}{h_1}}$$

which gives the ceiling of the machine in terms of the altitude h_1 at time t and the altitude h_2 at time $2t$. (Note that t may be any time whatever during the climb.) So all we require to calculate the ceiling of a machine is the altitude after any time, and the altitude after double that time.

We will now illustrate the foregoing analysis by a practical example. Observations of a certain aeroplane on a climb test showed the altitude to be related to the time after start according to the following table:

Time (minutes)—	0	2.5	5.0	7.5	10.0	12.5	15.0	17.5	20.0	22.5
Altitude (feet)—	0	3300	6150	8730	10760	12610	14190	15530	16650	17600

The ceiling of the machine may be calculated right away taking h_1 as 10760 ft. after 10 minutes and h_2 as 16650 ft. after 20 minutes. We have

$$H = \frac{10760}{2 - \frac{16650}{10760}}$$

$$= \frac{10760}{.4526} = 23{,}770 \text{ feet.}$$

We may next calculate T, the time constant. The value of the exponential (which we called X for short) is (when $t = 10$ minutes)

$$X = \frac{h_2}{h_1} - 1 = .5474.$$

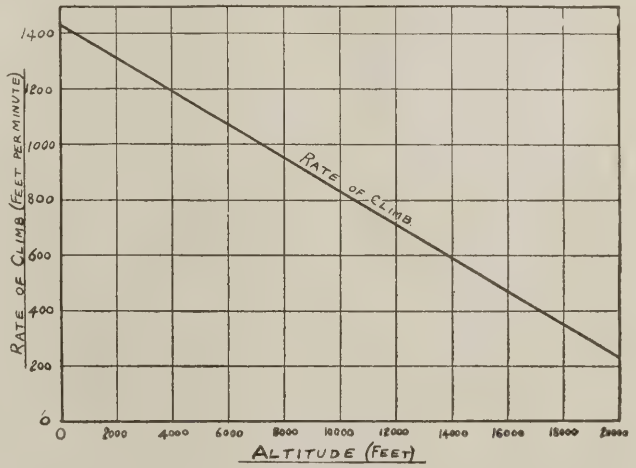
hence $\frac{10}{T} - = \log e\ .5474$

$= 2.3026 \log_{10} .5474.$
$= 2.3026 \times 1.7383$
$= 2.3026 \times = .2617$

whence $T = \frac{10}{2.3026 \times .2617} = 16.50$ minutes.

The initial rate of climb

$$= \frac{\text{ceiling}}{\text{time constant}} = \frac{23770}{16.60}$$
$$= 1432 \text{ feet per minute.}$$



Having calculated the constants of the climb, we may now write down the equations for the altitude at any time, the rate of climb at any time, and the rate of climb at any altitude. They are respectively:—

$$h = 23770\left(1 - e^{-\frac{t}{16 \cdot 60}}\right)$$

$$r = 1432\, e^{-\frac{t}{16 \cdot 60}}$$

$$\text{and } r = \frac{23770 - h}{16.60}.$$

From the first two equations the altitude and rate of climb at any time t are calculable and the figures for the altitude are found to agree closely with the table already given, so far as this table goes. We give below a table calculated from these two equations, also a table showing rate of climb at various altitudes. The results are also plotted in the accompanying curves.

Time (minutes)—	0	2.5	5.0	7.5	10.0	12.5	15.0
Altitude (feet)—	0	3320	6180	8640	10760	12575	14140

† The time required to rise to the ceiling is mathematically infinite.

NAVAL and MILITARY AERONAUTICS

Key to Abbreviations

AAD—Assigned to active duty.
ADO—Report to Aviation Supply Depot, Dayton, Ohio.
ADT—Report to Aviation Supply Depot, Dallas, Texas.
AEF—On duty with the American Expeditionary Forces.
AGC—Report to Aviation Supply Depot, Garden City, L. I., N. Y.
AHT—Report to Aerial Gunnery School, Houston, Texas.
AMV—Report to Aviation General Supply Depot, Morrison, Va.
AOV—Report to School for Aerial Observers, Hampton, Va.
APR—Report to School of Aerial Photography, Rochester, N. Y.
BST—Report to Brooks Field, San Antonio, Tex.
CAF—Report to Carlstrom Field, Arcadia, Fla.
CAG—Report to Camp Hancock, Augusta, Ga.
CAP—Commissioned as Captain, Aviation Section, Signal Corps.
CCI—Report to Chanute Field, Champaign, Ill.
CDT—Report to Aviation Concentration Camp, Dallas, Texas.
CGC—Report to Aviation Concentration Camp, Garden City, L. I., N. Y.
CGS—Report to Aviation Concentration Camp, Greenville, S. C.
CWJ—Report to Camp John Wise, San Antonio, Texas.
CLR—Commissioned as Colonel, Aviation Section, Signal Reserve Corps.
CMV—Report to Aviation Concentration Camp, Morrison, Va.
COL—Commissioned as Colonel, Aviation Section, Signal Corps.
CPR—Commissioned as Captain, Aviation Section, Signal Reserve Corps.
CRI—Report to Chanute Field, Rantoul, Ill.
CSO—Report to the Chief Signal Officer, Washington, D. C.
CUI—Report to School of Military Aeronautics, Cornell University, Ithaca, N. Y.
CWT—Report to Call Field, Wichita Falls, Texas
DAF—Report to Door Field, Arcadia, Fla.
DIK—Report to Camp Dick, Dallas, Tex.
DIS—Honorably discharged from service.
EEP—Report to Essington Field, Essington, Pa.
ELA—Report to Eberts Field, Loanoke, Ark.
EOT—Report to Ellington Field, Olcott, Texas.
FLR—Commissioned as First Lieutenant, Aviation Section, Signal Reserve Corps.
FLT—Commissioned as First Lieutenant, Aviation Section, Signal Corps.
FOB—Report to Fort Omaha Balloon School, Omaha, Neb.
FRF—On duty requiring regular and frequent aerial flights.
FSO—Report to Fort Sill School for Aerial Observers. Fort Sill, Okla.
GIT—Report to School of Military Aeronautics, Georgia Institute of Technology, Augusta, Ga.
GLC—Report to Gerstner Field, Lake Charles, La.
HHN—Report to Hazelhurst Field, Mineola, L. I., N. Y.
JHU—Report to School of Military Aeronautics, John Hopkins University, Baltimore, Md.
JMA—Rated as Junior Military Aviator.
JRC—Report to Jackson Field, Riverside, Cal.
KST—Report to Kelly Field, So. San Antonio, Tex. (When specified in the order, the number of the field is given in parentheses)
LDT—Report to Love Field, Dallas, Tex.
LHV—Report to Langley Field, Hampton, Va.
LTC—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Corps.
LTR—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Reserve Corps.
MAC—Report to March Field, Allesandro, Cal.
MAJ—Commissioned as Major, Aviation Section, Signal Corps.
MDO—Report to McCook Field, Dayton, Ohio.
MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MMP—Report to Middletown Aviation Supply Warehouse, Middletown, Pa.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PRC—Appointment to Aviation Section declined; prefers retaining previous commission.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
PWM—Report to Payne Field, West Point, Minn.
REL—Relieved from present duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRV—Report to Aviation Depot, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SAG—Report to Souther Field, Americus, Ga.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
TFT—Report to Taliaferro Field, Fort Worth, Texas. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UCB—Report to School of Military Aeronautics, University of California, Berkeley, Cal.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WAC—Report to Aviation Concentration Camp, Waco, Tex.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WFO—Report to Wilbur Wright Field, Fairfield, Ohio.

Note 1.—Report to points named for temporary duty in the order given.

Note 2.—Report to balloon detachment, Fort Monroe, Va.

Note 3.—Take station at San Antonio, Tex.

Note 4.—Take station at Ashland, Va.

Note 5.—Report to Signal Corps Recruit Bureau, Fort Wayne, Mich.

Note 6.—Report to district manager of equipment, 15 Park Row, New York, N. Y.

Note 7.—Report to Signal Corps construction troops, Fort Wayne, Mich.

Note 8.—Take station at Detroit, Mich.

Note 9.—Report to Major Arthur E. Wilbourn, Columbus, Ohio, for duty with board of officers.

Note 10.—Report to Walter Reed General Hospital, Washington, D. C.

Note 11.—Wire chief, military intelligence branch of executive division of the General Staff, Room 652, 1156 Fifteen St., N. W., Washington, D. C.

Note 12.—Report to aviation supply depot, Fairfield, Ohio.

Note 13.—Proceed to Cleveland, O., then to Capt. James G. Heaslet, 870 Woodward Ave., Detroit, Mich.

Note 14.—Report to manager of equipment, 870 Woodward Ave., Detroit, Mich.

Note 15.—Proceed to New York, N. Y., temporary duty; then to district manager of equipment, Buffalo, N. Y.

Note 16.—Report to Lieut. Fred G. White, 870 Woodward Ave., Detroit, Mich.

Note 17.—Report to Camp Alfred Vail, Little Silver, N. J.

Note 18.—Report to Madison Barracks, N. Y. for duty with photographic detachment.

Note 19.—Take station at Salem, O.

Note 20.—Report to Nordyke & Marmon, Indianapolis, Ind.

FOREIGN NEWS

DENMARK

The Danish Aeronautical Society is preparing for aerial mail services, which they hope will be carried into effect at the close of the war. Negotiations are pending with thirty-nine municipalities in the matter of constructing landing stations, including hangars 1,300 feet square. Routes from Copehagen to Odense, Frederica and Esbjerg, from Copenhagen to Kallundorg and Aarhus and from Copenhagen to Aalborg have been mapped out, and a route from the Danish capital to Gothenburg and Christiana are also planned.

FRANCE

The official war office announcement of April 29th reports the following aerial activity:

"Two enemy aeroplanes were brought down on April 27th. The same day our bombing 'planes dropped 6,000 kilos of projectiles on establishments in the enemy zone.

According to the announcement of May 1st, Sub-lieutenant Guerin brought down his twentieth enemy airman on April 30th. Sixteen of these have been brought down since December 1st, 1917.

Reporting on aerial activity, the French official communication of May 3rd states:

"Eight German aeroplanes were brought down on May 2, and twelve others, gravely damaged, fell behind their lines during a series of combats with our aviators. Effectual aerial bombardments were carried out during the day and night of May 2, 27,000 kilograms of projectiles being dropped on the railway stations at Ham, Nesales, Royes, Chaulnes and St. Quentin and upon bivouacs and cantonments in these regions. Seven thousand kilograms of bombs were dropped on enemy establishments in the region of Rethel and upon the railroad station at Asfeld-le-Ville."

The German aeroplane which was captured at Meaux, France, which had lost its way when attempting a raid on Paris, is a biplane of the A. E. G. type, fitted with two 260 horsepower engines, giving a maximum speed of 90 miles an hour. The pilot, through some miscalculation, thought himself over his own lines. He burned a flare, which was answered by one of the same color below. Upon seeing this, he landed his machine and its three occupants set out to ascertain their whereabouts. Soon they found themselves surrounded by a group of foresters and soldiers, who were guarding prisoners.

Reporting on the Macedonian situation, the Allied official statement issued from Paris on May 1st says:

"Numerous bombardments were carried out by Allied aviators. Two enemy aeroplanes were brought down."

On May 2nd, the following announcement regarding aerial activity on the Balkan front was issued:

"British aviators bombed the enemy's back areas. An enemy machine was brought down south of Gievgeli by a French aviator."

GREAT BRITAIN

The official announcement on aerial operations issued on April 30th says:

"East of Locre the enemy's troops on Monday (April 29th) offered good targets to our pilots, who dropped 275 bombs on them, and engaged them with machine gun fire.

"Seven hostile machines were brought down in air fighting, and one was shot down by our infantry. Two of our machines are missing."

Despite unfavorable weather conditions, the following aerial operations were announced on May 1st:

"Mist and rain again prevented flying Tuesday (April 30th), except for a few low reconnaissances in the course of which bombs were dropped on the enemy's troops between Locre and Voormezelle.

"One hostile machine was forced to land behind our lines. One of ours is missing."

The report on aerial operations issued on May 2nd says:

"One ton of bombs was dropped today at Thionville. Several bursts were observed on the barracks, railway stations and sidings. A fire broke out in the Carkshutte works."

More than fifteen tons of bombs were dropped by British aircraft at or upon the disabled Turkish cruiser, formerly the Goeben, which was taken over from the German Navy, while she lay aground at Navara Point, in the Dardanelles last January. Eight or ten aeroplanes were continually in action and two hundred and seventy-five aeroplane flights were made in an attempt to complete the destruction of the ship. On January 29th, a British scout machine sighted the Goeben in the Arsenal Dry Docks, at Constantinople.

The British official announcement of May 3rd reports intensive aerial activity, despite unfavorable weather conditions, as follows:

"A thick haze Thursday interfered with the work of our aeroplanes. Three and a half tons of bombs were dropped on Bapaume and other targets in the battle areas. At times the fighting in the air was severe.

"Fourteen hostile machines were downed and four were driven down out of control. Five of ours are missing.

"During the night five and a half tons of bombs were dropped on Chaulnes, Juniville, the railway junction at Bapaume and at Caix. Three very large bombs were also dropped from a low height on the lock gates at Zeebrugge.

"Friday another successful raid was carried out against the railway station and sidings at Thionville. The Carlschutte works again were hit and several bursts were seen on the station, sidings and gas works. All our machines returned."

The British official statement issued on May 4th reports the following aerial operations:

"A most successful day's work was accomplished by our aeroplanes Friday, good visibility assisting co-operation with the artillery. Bombing was carried out with the utmost vigor. Over twenty tons of bombs were dropped on the Chaulnes, Tournai and La Bassee railway stations and on Estaires, Marcelcave, Menia, Comines and Middlekerke.

"Fierce fighting continued all day. Twenty-eight German machines were brought down, five were driven down out of control and three were shot down by anti-aircraft guns inside our lines. Eleven of our machines are missing.

"After dark a thick mist set in on most parts of the front. Over two tons of bombs were dropped, however, on the Chaulnes and Juniville railway junctions. In spote of the very bad weather, all our machines returned."

An Associated Press dispatch, dated May 4th, reports from Dutch sources some of the results of the persistent Allied air raids. According to *Les Nouvelles* of The Hague, Allied aviators recently sank in one day twenty-one Belgian boats, laden with gravel and road metal for the German front at Picardy. Two arches of the Namur bridge were destroyed several weeks ago. Roads have been cut up so that the Germans have experienced great difficulty in bringing up sufficient gravel and stones to fill up the craters. From the same source, it is stated that Allied aircraft destroyed the railway station at Hainaut, Belgium, resulting in the destruction of a forty car train of munitions and the loss of many Germans.

An Associated Press cable reports several attacks on Dutch fishnig vessels by German seaplanes.

Captain Stanley Rosevear, Canadian aviator in the Royal Flying Corps, was killed in action on April 25th. He was one of Canada's foremost aviators, having brought down twenty-one German airmen single-handed. His record included three scores a day on two occasions and ten scores in eleven consecutive days. He had been awarded the D. S. O. with bar.

The Victoria Cross has been awarded to Lieutenants Allan Gerrard and Alan Arnett McLeod of the Royal Air Force for their remarkable feats of airmanship. Gerrard, when on an offensive patrol with two other officers, attacked five enemy aeroplanes, shooting one down in flames. He then attacked an enemy aerodrome, engaging single-handed some nineteen machines, which either were landing or starting off, and crashed one of them against the aerodrome. Seeing one of his companions in difficulty, Gerrard went to his assistance, and downed a third enemy. Finally, overwhelmed by number, Gerrard was forced to retreat.

McLeod, while flying at an altitude of 5,000 feet was attacked by 8 enemy machines. By skilful manoeuvres, , he was able to shoot down three of his opponents. Both his observer and McLeod were wounded by the enemy, and their machine was in flames, but McLeod returned safely to his own lines.

Educational lectures on aircraft topics are being given in London, Leeds, Lincoln, Coventry, Norwich and Peterborough under the auspices of the Aeronautical Society of Great Britain. The subjects of the lectures and the lecturers are: "History and Development of the Aeroplane," by Captain F. M. Green; "The Aerofoil and Fluid Flow Round Bodies," by E. F. Reis; "The Air Screw," by A. Fage; "The Modern Aeroplane," by F. H. Branwell; "Materials and Methods of Design in Construction of Aeroplanes," by J. D. North; "Industry and Development of Baloons and Airships," by Commander W. Lockwood Marsh; "Constructional Methods, Airships and Balloons," by Wing Commander J. N. Fletcher; "Stability and Control," by Captain R. F. C. Aston; "Airships," by Captain J. S. Irving; "Meteorology and Navigation," by Professor W. G. Duffield.

According to an article in one of the London papers, experiments are being made to produce the planes of flying machines from aluminum wire mesh fabric, filled with a cellulose acetate film.

During April, 585 aeroplanes were reported downed on all battlefronts. This was somewhat more than half of the total in March, which was 1,059, the highest aggregate during the war. Of the total of 585, the Allies claimed 470 and the enemy 115. More than half of the Allies' total, 278, fell to the guns of British pilots, infantry or anti-aircraft guns. Against this, 75 British machines were lost, 172 German aeroplanes were downed, 22 fell to gunfire, and one large bombing machine was captured intact. Although these totals indicate less activity than the previous month, on April 12th, 40 German machines were destroyed by British pilots, 20 driven down out of control, and 2 destroyed by anti-aircraft artillery, making a loss on that day to the enemy of 62 machines.

ITALY

The War Office at Rome included the following statements regarding aerial activity in the announcement of May 2nd:

"Italian aviators brought down three enemy aeroplanes. British airmen brought down two others."

"Greater aerial activity than usual is indicated by the official Italian announcement of May 3rd, which states:

"On the whole front there was intense aircraft activity. Eight hostile machines are reported to have been destroyed."

A more complete description of the operations of May 3rd is contained in the night report, which supplements the above:

"Our flyers destroyed twelve enemy aeroplanes. We lost three machines. The total number of enemy aeroplanes destroyed since the arrival of the British in Italy is 109. In the same period we lost 13."

On May 4th, the Italian War Office issued the following statement regarding aerial operations:

"Aircraft actions were carried out despite the enemy's attempt to oppose them. The British dropped sixty bombs on hutments in the Assa valley. An Italian airship dropped a ton of explosives on the aviation ground at Camp Maggiore. Fourteen hostile aviators were brought down."

Increasingly intensive aerial operations are described in the War Office statement issued from Rome on May 5th:

"The activity of our aircraft has been intense. Caproni flights and British aeroplane, protected by numbers of chasers, dropped about nine tons of bombs on the hydro-electric works at Cavedin, north of Mori. While this operation was in progress other machines renewed the bombing of the aviation ground at Campo, Maggiore, south of Lenico.

"Last night our airships, reaching by surprise the railway station at Primolano and Bolzano, dropped their loads of bombs with good effect. At the same time an airship of the Royal Navy engaged enemy columns on the march beyond the Tagliamento.

"Eight enemy machines were reported destroyed, two of which fell in flames within our lines."

IN making my acquaintance with the readers of this page, I want it to be understood that in future "MODEL NEWS" will contain instructions for building models and model motors, in addition to the usual notes of model contests, photographs of new models and general information.

Starting with the next issue of this paper, I will begin a series of articles on the construction of model aeroplanes, starting with the simplest of rubber driven models, and with each succeeding issue, gradually work up to the construction of engine driven models. When we think we have mastered the full scale, engine driven model, we will go a step further to the man carrying glider, and thence to the light horse powered man carrying machine.

Some model makers have an idea that in order to construct an engine driven model it is necessary to have a fully equipped machine shop. I wish to correct this impression at once. It is only necessary to have a file, good drill press, a small riveting hammer, alcohol lamp and a good vise. (When we get to making engines, I will give instructions in adopting the tools I have just mentioned to different kinds of machine tools, such as a hand lathe, metal spinner, grinder, etc.)

In order not to hold back the more experienced model flyer while the simpler models are being described, I will have articles interesting to him as well. Before the end of the year, I hope to have all the model readers constructing engine driven models, or the large machines. It was through the model aeroplanes made by Prof. Langley and the Wright Brothers, that aviation became a reality, who knows, but some of our readers, through experiments with models of their own construction will, by chance, hit upon something that will revolutionize the whole aeroplane industry. I might call attention to the fact, that all the old model flyers have benefitted by their experiments with models, inasmuch as most of them are holding responsible positions with large aeroplane companies, or have received commissions in the service. If I were to list the names of all the model flyers who have made good, this page would not be large enough to hold them. Each and everyone of you have the same chance. The model flyers of today are the big aircraft men of tomorrow. If at any time you have difficulty with your models in the way of constructing, balancing, or something you cannot overcome, or if you have any suggestions to be made, don't be a bit backward in sending ideas to me. If you have any photographs of successful models that you think others would like to see, please send them to me with full description for publication.

MODEL EDITOR.

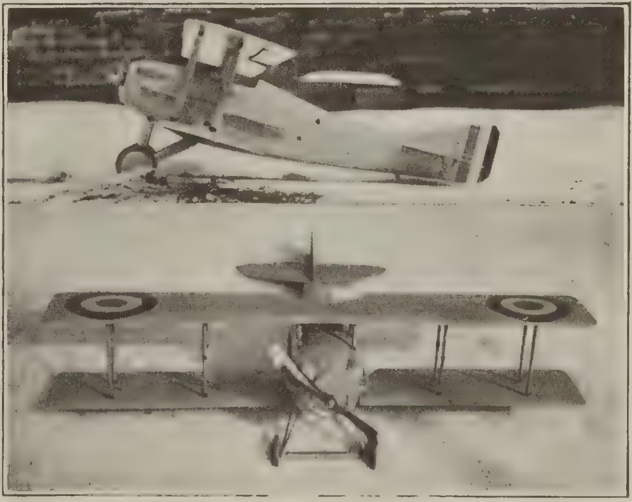
Interesting "Spad" Model Made of Wood

The Spad model shown in the accompanying illustrations is made of wood, and true to scale, being one inch to the foot. It is finely constructed and when placed on exhibition attracts a good deal of attention. It is very scrappy in appearance and has a miniature Lewis machine gun mounted on the fuselage immediately in front of the pilot. For those who care to construct a model of this kind the directions are as follows: The body is made from a piece of soft white wood free from knots and after marking out the general outline of the fuselage (the streamliners behind the pilot's head and over the engine cylinders can be made separately and glued on later, then shaped to fit), shape roughly with sharp knife or chisel after which it may be planed and sandpapered. The pilot's cockpit is just a hole 2" in diameter, a seat may be inserted. This can be made from cardboard and painted to represent aluminum, a large upholstery tack may then be placed behind the pilot's head about the centre of the streamliner.

The wings are made from ¼-inch white wood, after shaping to a perfect wing section (the Spad being a fast machine the bottom may be left flat, only the top being cambered), then drill 3/16" holes at points where struts are to be connected. Struts are made of ¼-inch dowel sticks but planed and sandpapered to a perfect stream line shape. The struts for the landing chassis are cut from white wood on account of the thickness and are made in one piece, a ⅛-inch hole being drilled through each at the apex of the V's for the axle. A streamliner of wood is made around the axle; the wheels are alinum disc 2" in diameter.

The rudder, fin, tailplane and elevators are made of ⅛" wood. The entering edges are rounded off with sandpaper, the trailing edges are shaped more to a knife edge. The exhaust pipes on this model are made of copper tubing, but they may be made of reed ¼" diameter.

To assemble, drill holes in the fueslage for top plane struts, and glue struts in place, next glue top plane in place. When glue is set turn model on its back and glue the bottom plane in place, butting it against fuselage. To make this joint stronger a metal clip should be nailed to bottom plane and fuselage. The rudder, fin, and tail are glued and nailed in place. The landing carriage is next placed in position by glueing the struts in holes drilled in bottom of fuselage. As no wires run to the elevators or rudder on the Spad this makes a very clean job. Before wiring between the planes it would be better to paint the machine as it is much harder to do this after wires are in place. The machine should be painted a silver grey or sky blue. Black paint should be used to represent fittings. To make the model look more like its prototype, paint the French insignia blue, white and red circles on the planes, and stripes on the rudder.



Two views of a Spad scale model as described above

Aeronitis

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

Are You Insured?

Are you insured? It's really a vital question,
If not, you should be, but 'tis only our suggestion.
For if you ride to work each day upon our yellow cars
By this time you must be well nigh full of scars.

Some mornings back the steering broke, oh yes, we came off well,
But another time we might not, for never can we tell,
Of course this won't occur again, for they've tied it up with wire,
And if you say that's not much good, they promptly call you l—r.

Another day a wall we cannoned, such an awful knock,
The men just did a shudder, but the ladies got "some" shock.
O'er stones and mud we lumbered till the Works they hove in sight,
But it took us nearly all that day to recover from the fright.

Not long ago, while riding with the 'bus in concert pitch,
An "Indian" o'ertook us, then we all went in the ditch,
So out again we clambered with sundry cries and groans,
And set off to the Works on foot, in spite of bruised bones.

Now don't you think it would be wise before things get much worse,
In case some day, after a spill, you go home in a hearse,
Don't think we wish to make you sad, yet knowing not our fate,
We suggest, get insured for a good round sum before it is too late.
"ISO."

Guaranteed!

Novice: "Suppose when I get up two thousand feet in the air this monoplane suddenly falls."

Salesman: "We warrant all our goods. You can bring it back."—*Lehigh Burr.*

Good Advice

He who courts
And does not wed,
Often goes
To court instead.
—*Penn State Froth.*

Back from the Front

"Rastus, is my bath warm?"

"Yassah, the warmest Ah was evah in."—*Harvard Lampoon.*

That's It

Visitor: "I don't see how the airmen can keep their little caps on their heads."

Instructor: "Vacuum pressure."

To the Latin Department

Giveit tu em gudant plenti,
Soc et tu em gudant strong,
Never letem geta stand in,
Gopher evri word that's wrong.
Makem flunk and makem worry,
Makem sit up nights and buck,
Makem wun derwat cher thinking,
Makem cursther evilluck.
Never letem getoo hopefull,
Never sayther doing well,
Makem wish they hadn't cum here,

A few suggestions for manufacturers' after-war designs, to suit all sorts and conditions of sporting followers of the art of aviation.

Gillette Safety Razor

Have You Seen the New Gillettes Specially Designed for the Fighting Man?

THESE models were designed by members of the Gillette Organization who have seen service with the Colors and know what the soldier is up against.

Hundreds of officers and men are buying them—the U. S. Service Set in metal case, and the new Khaki-covered sets for Uncle Sam's soldiers and officers.

The Gillette is the one razor for the man who is doing things—the one razor with world-wide use and reputation.

When a man wants new Blades he can get them at any Post Exchange or Y. M. C. A. Hut—here in America or Overseas.

Our Paris Office carries stocks—is constantly supplying the American Expeditionary Forces. Gillette Safety Razors and Blades on sale everywhere in France, England, Italy and the Eastern battle fronts.

The Gillette Is the Real "Once-Over Razor" of the Fighting Man

THE Gillette Safety Razor has been carried in the breast pockets and in the kits and ditty boxes of hundreds of thousands of keen, alert fighting men on every front and on every sea.

It's made good—under conditions that have sent nearly every other kind of razor into the rubbish heap.

The Gillette is bringing shaving comfort to thousands of men in the Service—no matter how wind-tanned and sun-burned.

Every man in the Service—or every man who's going Overseas—needs a Gillette. The new U. S. Regulations require the boys to keep clean-shaved.

The Gillette makes it easy. It delivers a velvet-smooth shave with any thickness of beard or skin, with hard or soft or hot or cold water. No strops or hones to clutter up the kit. Blades always sharp, always ready. No Stropping—No Honing.

AND THE SAVING

You save 25 per cent in power alone.

You save countershafts and care of them.

You save the cost of belting.

You save floor space—gain in overhead room and more light.

You save wear in cylinder journals and boxes caused by belt pull.

You can run this machine at night without running a lot of shafting.

You can place it where your lumber can be handled most conveniently, regardless of line shafting.

(*Continued from page* 441)

unless an allowance is made to officers, when they will be expected to get khaki uniform as soon as possible.

The cap will be of the same pattern as that worn by the R. N. A. S. The crown is khaki, and the peak and band are black. The badge is entwined laurel leaves, above which is a reduced fac-simile of the metal bird at present worn on the sleeve by the R. N. A. S., the whole being surmounted by a crown. Rank is denoted as follows:

Second lieutenants and lieutenants, one upright metal bar on each side of the badge.

Captains, two upright metal bars on each side.

Field officers, one row of gold oak leaves on the peak.

General officers, two rows of gold oak leaves on the peak.

The jacket is that of the military tunic service dress, modified as follows: (a) No shoulder straps; (b) in lieu of Sam Browne belt, a cloth belt is sewn on the back of the coat, which fastens in front with a bright buckle of gilt metal; (c) the buttons are the R. N. A. S. type, *i. e.*, gilt metal with bird surmounted by crown.

RANK DISTINCTION

Officers transferring from the R. N. A. S. and the R. F. C. will, on supplying themselves with Air Force uniform, wear rank distinction corresponding to that which they hold in their present service, whether their present rank is permanent or temporary. The badges of the Royal Navy in khaki braid will be used, with a bird surmounted by a crown, both in gilded metal. Second lieutenants will have no distinction lace, but the bird and crown on both sleeves. Higher ranks will wear distinction lace surmounted by the bird and crown, as follows: Lieutenant, one row; captain, two rows; major, two and one-half rows; lieutenant-colonel, three rows; colonel, four rows. Generals will have lace as follows, surmounted by the bird and crown: Brigadier-general, one broad row of 2¼-inch lace; major-general, one broad row and one ordinary row of distinction lace; lieutenant-general, one broad and two ordinary rows of distinction lace; general, one broad row and three ordinary rows of distinction lace.

Trousers and breeches will be as now worn by the R. F. C., with khaki shirts and collars with black ties. For footgear the following is prescribed: With breeches—Brown field boots or brown boots with puttees or gaiters, or brown stockings with shoes for aerodrome and similar wear. With trousers—Brown boots or shoes with brown socks. The usual military type British arm for mounted services will be worn. Badges of rank will be indicated on the shoulder-strap in the same way as on the jacket, by distinction lace surmounted by bird and crown.

VENUS PENCILS

YOU'LL have to do considerable drafting and sketching—maps, engine design, speed curves, test charts, etc.

VENUS Pencils are wonderfully smooth, even, easy-marking and you can get just the degree which is ideal for the work you have to perform whether this requires the heaviest and blackest or the thinnest and cleanest of lines. *VENUS Pencils are the world's standard for all technical work.*

For sale everywhere in the U. S. as well as in England and France.

Fit for Anything

(Editorial in New York *Tribune*)

ANOTHER American, an automobile racer, Rickenbacher, has been added to the list of trained athletes who have distinguished themselves in the air. The list is a long one, but it is no whit longer than that of plain civilians, with no noteworthy record as athletes, who have developed into crack fliers. Guérin, the most promising of the newer French fliers, was a clerk in a Havre shop. So runs the story in every camp and cantonment.

The moral is fairly plain. Athletic prowess is a help, but it is not indispensable. What are absolutely necessary are the sound heart and lungs and nerves which come only from good, husky health, won and preserved by a reasonable attention to bodily needs. Such equipment does not necessarily belong to the crack athlete who has rowed his four-mile races or done his hippodrome stunts. The call that war issues is for sound, all-round physical development—not so much excessive muscular training as good, open-air exercise week by week.

Universal military training would go far to answer this call. So would an increasing sense of national obligation to be strong, to be fit, to be ready for a fight or a frolic. The lesson is one that we can all study and digest for use in the days ahead when we are planning the upbringing of future generations in a world that, however safe for democracy, will never be wholly safe for the defenders of democracy.

against the strut. The designer of the machine could affect the design of the jig in many ways. In the case of a wing section in some designs the spars were set at any angle to suit the particular section of the wing which had been chosen, rather than to adjust the section in the vertical plane for both spars. If the designer thought more about the design of the jig when getting out his designs it would simplify the production of the machine to a great extent.

Mr. Gillingham said he had known wood to contract 1-10th inch in 20 ft., and therefore he did not understand how the A.I.D. could expect to get a limit of plus 1 or minus 1. There was a good deal to be said for jigs in certain forms, but wood could not be stopped from shrinking. If the A.I.D. used a little more—should he say practical knowledge—it would facilitate the output of aircraft.

Lieutenant Crossley, R.F.C., said he thought if the foremen in the works and the tool-room foreman worked together more, the jigs obtained would be more effective. Their combined experience would lead to a much better effect. The tool-room drawing office should work more with the shop foremen, and get their experience of faults found in previous tools and jigs.

Mr. Sumner said centralization of design rather assumed finality in aeroplane construction, whereas ideas should be encouraged on the part of sub-contractors and others. The discussion rather took the line that the man who designed aeroplanes could also design jigs, but it required a different training and practice. The tool maker, the constructor of the machine, and the man who was going to use it should all confer, and put all points right at the outset rather than wait till later.

Mr. Alton said he thought most of the aeroplane designers and draughtsmen had come from the automobile industry and tool shops, and knew little of the vagaries of wood, which frequently changed its dimensions 1-10th in. between the woodworking table and the assembling shop. Metal parts were made with tolerances of thousandths of an inch; when used in conjunction with wood they should rather be in tenths of an inch. Metal parts made in thousandths were sometimes sent back for alterations of some tenths to make them fit the wood parts. It was often the faulty design of the metal parts which called for so much alteration in the assembling of the whole machine.

Mr. Winship said, in view of the reduction of the number of skilled hands and the employment of women, cramps would have to be used in jigs with stops to prevent the women cramping the timber up too tightly.

Mr. W. E. John thanked the author for the valuable information he had given that evening. Whilst fully appreciating the value of the use of jigs and fixtures in the manufacture of aeroplanes, he drew attention to a small point in this connection which had not previously been referred to. One of the gentlemen representing the A.I.D. had stated that they advocated the extensive use of jigs and fixtures, since it reduced their work to a large extent owing to the greater accuracy of the parts produced. It must, however, be remembered that jigs and fixtures are generally used by unskilled labor. An unskilled workman operating an inhuman machine, such as a jig, provided with some of the cramping devices shown on the screen that evening, will lack the "feel" possessed by a skilled craftsman and will not realize what harm he may be doing to some parts he is handling. A man working with wood all his life acquires a sense of touch which will warn him at once if by chance a part is over stressed when he is bending it or even when he is placing it in the jig. The part may perhaps possess some invisible flaw. If he is a conscientious workman he will throw such part aside. If, however, he has not had the experience, without realizing there is anything amiss, he will build the part into the machine, and it will take the best inspector all his care to detect the fracture. For this reason, therefore, he wished to point out that with the increasing use of jigs and fixures more attention must be given to the thorough instruction of the operators using such jigs and fixtures.

The Chairman (Sir Henry Fowler) said Mr. Matthews had mentioned that to have a machine jigged properly about 1,200 jigs were required. In the present state of the labor market this was a very serious matter. The time would undoubtedly come when constructing machines on a commercial rather than on a war basis, when what Mr. Matthews had demonstrated would grow to a very large and interesting state, and would be one of the most interesting propositions that had ever come before engineers. There was a difficulty at present in getting sufficient jig makers and draughtsmen.

Mr. R. Borlase Matthews, in reply to the discussion, said that if a factory had a proper jigging system, the jigs succeeding

each other became self-jigs, and if a man strained a piece of wood by forcing it through one jig, the false work would probably be discovered when it was fitted in an assembly unit. He did not think inspectors would be out of work by any means if everybody jigged, as the jigs would have to be inspected from time to time on account of wear. He did not mean to say there should necessarily be one universal jig office. That would be too big a scheme with the present shortage of expert jig draughtsmen. Rather he intended to convey the importance of associating a jig designing office with each firm of aeroplane designers. This jig designing department should supply drawings of jigs for all the aeroplanes designed by the firm to the sub-contractors making each particular machine. The wood-working for aeroplanes had been developed largely by people who had been in the furniture and other wood trades, and they could not be expected to become experts immediately in the aeroplane business. Hence, any assistance that could be rendered in the shape of drawings of jigs should be given, though the designs need not of course be followed in minute detail. Even with the drawings as a basis, there was ample scope for ingenuity and initiative in the construction of the actual jigs. However, at the moment, jig drawings were conspicuous by their absence. He did not intend to despise the skill of the foremen. He meant to say that the main scheme should be laid out on scientific lines before placing the work in the shops, and if the foreman ran short of a special kind of wood or the like, it was up to him to make the necessary modifications, or if he wanted to substitute certain metal fittings for wood, there was no reason why he should not apply the scientific principles that had been laid down. One manufacturer in this country had found it worth while to lay down 5,000 jigs to make one machine, and, as he had pointed out in the paper, the thing was a business proposition.

He knew of a case where the Services decided not to introduce any modifications into a machine, and in a short time they received a couple of hundred modifications from the manufacturer himself. A question to be considered was how long it would be before wood was replaced by metal in aeroplane manufacture.

He had seen vertical jigs for plane manufacture. They were very compact, and constructed entirely of metal.

For wood that had been properly seasoned, either naturally or artificially, he saw no difficulty in fixing limits, and in working to those limits. American and German manufacturers had devoted greater attention to the manufacture of jigs, than had those in this country, although some of our manufacturers moved with the times.

One outstanding feature of the aeroplane industry was that a very large number of difficult problems had been presented, which have had to be most carefully considered. Incidentally, these problems had brought out much ingenuity in their solution. An example, to which reference had been made in the discussion, was the special type of gauge for measuring lengths, devised by the A.I.D.

(*Continued from page* 450)

I fear, unless something of this nature is done, failure in this great department and publicly investigated scandal will result, which, stepping upon the heels of preceding scandals, will accomplish little of a corrective nature—but further delays in this important work.

I believe that you might seize this whole bankrupt program, present the situation to the Senate Military Committee, request abeyance of its investigation, complete what is here begun, and then, under your own guidance, urge the Military Committee to prosecute its inquiry to the end—with your aid and direction.

This has seemed to me to be the constructive plan, to be the harmonious plan, that would result in rebuilding, would give us time to correct the present ills, and with men who desire it we can still deliver some machines in Europe. Sincerely and faithfully.

Gutzon Borglum.

THE FIRST AERIAL MAIL

THE inauguration of the first aerial mail line happens on the very day when Aerial Age is on the presses and we are holding up the printing long enough to include a brief report of this epochal event.

Fortunately, the weather was fine, and everything carried out successfully.

The aeroplanes employed were loaded with mail to their full capacity. Government, state and aeronautic authorities attended the inauguration at New York, Philadelphia and Washington.

The New York party included Postmaster Patten, of New York; Hon. Byron Newton, Collector of the Port of New York, who delivered an address; Mr. Alan R. Hawley, who also delivered an address and Hon. Murray Hulbert, Dock Commissioner; Admiral Fiske, Mr. Glenn H. Curtiss, Henry Woodhouse, Lieutenant Henry Farré, Lieutenant Santiago Campuzano, Lieutenant Dobbel, Professor Charles L. Poor, Mr. William Hawley, Mr. Leroy B. Gulotta, Mrs. Wm. A. Bartlett, Chairman Aviation Committee, National Special Aid Society; Mrs. Henry A. Wise Wood, and Mrs. Charles A. Van Renesselear, vice-chairman and chairman of the National Aeronautic Committee of the Woman's Naval Service, respectively; Miss Alice Carpenter, vice-chairman of the National Committee on Comforts and Recreation; Mr. G. Douglas Wardrop, editor of Aerial Age; Mrs. C. Lansing Baldwin, Mrs. Edward Robinson, Mr. Charles Jerome Edwards; Mr. Evan J. David, business manager of *Flying;* Mr H. B. Childs, and Mr. E. H. Felix.

Mr. Hawley's Speech

In the course of his speech Mr. Hawley said:

"The inauguration of the first aerial mail line is an epochal event, as well as a most important step towards solving certain problems connected with the upbuilding of our aerial forces and meeting a condition which is just beginning to shape itself and which may in a year or two become most serious.

"This day will go down in history as marking the advent of a new epoch, because this New York-Philadelphia-Washington aerial mail line is the forerunner of a network of aerial mail lines which will cover the entire world and will be a dominant factor in the reconstruction that will follow the war.

"Progress in aeronautics in the past eighteen months has been enormous. The marvelous flights of the giant Caproni and Handley Page air cruisers give an idea of what we may expect in the coming twelve months. The flight of one thousand miles without stopping made recently by a squadron of Caproni triplanes, and the flight of a Handley Page biplane from London to the Dardanelles, two thousand miles, with several stops but no mechanical trouble, carrying five passengers and spare parts, complete camping equipment, provisions and bombs, are but some of the hundreds of such performances. These huge warplanes were, indeed, the backbone of the Allied forces in the recent desperate German drive and it is generally stated by the Allied strategists that had the Allies had one thousand more of these huge warplanes they could have prevented the drive. They would have destroyed the bridges on the Rhine and prevented the accumulation of German troops and war materials; they could have attacked troop formation and batteries with bombs and guns, and destroyed munition dumps—and in other ways weakened and harrassed the Germans.

"The tendency is towards large machines—larger and larger. I feel certain that before the year is over we shall see aeroplanes equipped with over 2,000 h.p.—which will be capable of flying across the Atlantic.

"Postmaster General Burleson and Mr. Praeger and the other military and civil authorities who are co-operating in making this aerial mail service a success are to be congratulated for their progressiveness."

In the mail which arrived from Washington, Mr. Hawley received the following letter from Postmaster General Burleson:

May 15, 1918.

MR. ALAN R. HAWLEY,
President, Aero Club of America,
New York City.

My dear Mr. Hawley:

The Aero Club of America naturally will share the pride we all feel in the inauguration today of a permanent aeroplane mail service.

Your efforts in fostering the development of aeronautics in the United States is rewarded by this new achievement.

I anticipate that the aeroplane will be as successful in the service of communication and commerce as it has been in furnishing the eyes and the fighting dart of the sky in the time of war.

The aeroplane mail service should be of great practical value, and it is believed that today marks the beginning of an epoch in the development of a speedy mail communication.

Sincerely yours,
(Signed) A. S. BURLESON.

SENATE AND DEPARTMENT OF JUSTICE INVESTIGATING AIRCRAFT SITUATION

ON May 9th Senator Chamberlain, Chairman of the Military Affairs Committee, put in his resolution to give sanction to the investigation into the aircraft situation. The resolution, which was referred to the Military Affairs Committee, follows:

Resolved, That the Committee on Military Affairs, or any sub-committee thereof, be and is hereby authorized and directed to inquire into and report to the Senate the progress of aircraft production in the United States, or into any other matters relating to the conduct of the war by or through the War Department; that said committee, or any sub-committee thereof, may sit during the sessions, or during any recess of the Senate; to require by subpoena or otherwise, the attendance of witnesses and the production of books, documents, and papers; to take the testimony of witnesses under oath, either orally or by deposition; to obtain documents, papers, and other information from the several departments of the Government, or any bureau thereof; to employ stenographic help, at a cost not to exceed $1 for printed page, to report such testimony as may be taken; to employ such agents or assistants as may be necessary, and that all expenses, including traveling expenses, contracted hereunder shall be paid from the contingent fund of the Senate.

On May 6th, President Wilson, following a period of charges and counter charges regarding the aircraft situation, turned the whole matter over to Attorney-General Gregory, who was instructed to make a thorough investigation of the "wholesale charges" in regard to the production of aircraft made by Gutzon Borglum, the sculptor.

Progress of the Aircraft Discussion Chronologically

May 7

Mr. Borglum's letter of May 6 to the President reiterating his charges and attacking War Department officials for hampering him in his efforts to establish the truth not only caused the Senate committee to determine to pursue its own investigation regardless of the Department of Justice inquiry, but also brought a renewal of the attack on the aircraft program from both sides of the Capitol.

Senator Chamberlain made known the determination of his committee to conduct its own investigation in a fiery speech which stirred the Senate and which was provocative of a debate in which more of the delinquencies and delays were gone over. At the same time W. C. Potter, chief of the equipment division of the Signal Corps, was testifying before the House committee.

Attorney-General Gregory upon leaving the Cabinet meeting declared that his investigation would be an exhaustive one and that he already had the Borglum and the Marshall reports. Assistant Attorney-General Frierson was assigned to conduct the investigation.

"Mr. Borglum," said the Attorney-General, "will have every opportunity to make good his charges. We are not going to investigate the merits of the Liberty motor, but we shall determine whether or not there has been malfeasance such as has been charged."

A contract has recently been cancelled for approximately 5,000 Liberty motors, and the factories assigned to their production will make French motors of the Bugatti and Hispano-Suiza type.

The following facts also were developed at the executive session of the House committee.

This country has in France about 1,200 aeroplanes, but the majority of them are training planes and are of English and French manufacture. There are only a few dozen Liberty motors in France.

The aviation service has expended or contracted for the entire $740,000,000 appropriation given by Congress at the last session, and to-day presented a deficiency estimate to the House committee.

For this huge sum there have been produced in this country about 5,000 planes within the last year. Nearly all of this number are training planes, and a very few are equipped with Liberty motors. William C. Potter was quoted as saying to the House committee to-day that "the Liberty motor is still in the process of refinement and perfection."

Simultaneously Mr. Potter, a civilian but recently assigned to the equipment task, told the House committee that unquestionably a great deal of valuable time has been sacrificed in experimentation and necessarily large sums of money have likewise been sacrificed which might have been saved by the earlier manufacture of foreign motors.

Baker Asks Secrecy

At the morning session of the House committee Secretary Baker was present. The Secretary asked the utmost secrecy for the army's aviation program and the estimates for $1,032,000,000 submitted by the War Department.

About a dozen officers of the Signal Corps, including Major-General Squier and his immediate assistant, Brigadier-General Saltsman, were present at the hearing, but Mr. Potter and Brigadier-General William L. Kenley, chief of the aeronautical division, occupied most of the time. John D. Ryan, newly appointed head of the Aircraft Production Board, did not testify, although present.

Action on Pershing's Advice

In ordering the cancellation of large contracts for Liberty motors and the substitution of the Bugatti and Hispano-Suiza motors the War Department acted on direct advices from the western front, in which advices it is understood both the French, English and American commands concurred.

This cancellation, it was explained, does not mean that the Liberty motor is a failure, but its use is to be restricted to "heavier purposes," and it is not the ideal motor for combat and pursuit. The large 'plane which necessarily must accompany this motor, it was said, makes it unsuitable for speed purposes.

The Duesenberg Company and the Wright-Martin Company have been given contracts for the substitute production of the French motors.

A shortage of spruce and the shipment of four-fifths of the spruce supply of this country to the Allies within the past year were advanced as partial reasons for slow production.

General Accounting Made

Figures presented to the House Military Affairs Committee by W. C. Potter, Chief of the Equipment Division of the Aviation Section, United States Army, convinced members that much of the criticism leveled at the Administration would not have arisen had the War Department officials frankly explained from time to time the difficulties encountered in aircraft production.

So far as could be learned, the $740,000,000 apportioned for aviation has been expended as follows:

The War Department has expended $307,000,000 for aeroplanes and fields.

There is an unexpended balance now on hand of $433,000.000.

Of the unexpended balance, all is covered by contract, and additional contracts have been let for machines and other equipment which provide for expenditures of $148,000,000 beyond the appropriation.

The money already expended has been used as follows:

For engines and aeroplanes and general machine equipment	$163,000,000
For hangars and the acquirement of aviation fields in this country	42,000,000
For aviation fields and other purposes in France	31,000,000
For gas balloons	5,000,000

There is $31,000,000 in the hands of the Disbursing Agents and not reported at the hearing.

The balance has been spent for miscellaneous aviation work, for experiments and other general expenses connected with the program.

Liberty motors are now being made at the rate of 100 a week, Mr. Potter informed the committee.

The Government has ordered 14,000 foreign planes, and 1,800 have been delivered, he said, while 8,000 foreign engines have been contracted for, the deliveries amounting to fewer than 1,500.

There are between 1,200 and 1,400 aviators actually flying with the American forces on the western front.

There are 5,000 men physically fit and ready to enter the service, while there are 15,000 flying and non-flying aviation service officers in the United States and France.

In the Signal Corps to-day there are 133,000 men and officers, which exceeds the strength of the regular army when this country entered the war.

Senator Chamberlain's Speech

Senator Chamberlain surprised the Senate in the suddenness with which he proclaimed the intention of the Military Committee to plunge again into the maelstrom of an investigation. He said:

"I feel impelled to make a few observations in view of the letter from the President to the Senator from Colorado. I have never seen the Borglum report referred to therein. I have never had any conversation with Mr. Borglum, although I saw him a little while yesterday in the committee room in company with a few other members of the committee.

"I infer in a general way from the statements published with reference to the Borglum report that it had reference more particularly to dishonest transactions or transactions of a pro-German character affecting the general work of the Aircraft Board. Whether that is true or not I do not know.

"I should like to see that report and shall make an effort to read it as well as the other report bearing on the same situation. The Committee on Military Affairs some time ago made a general report dealing in a general way with aeroplane production without going into details as to the expenditure of particular sums of money by the Aircraft Board or by any of those associated with it in aeroplane construction.

Conclusions All Agree

"It is only necessary to say that the conclusions of the committee were the same as those which were reached by the Marshall committee, which investigated the subject at the request of the President. The same conclusions reached by the Marshall committee and the Committee on Military Affairs were reached also by Mr. Borglum; in other words, that there ought to be a change in the method of aircraft production, that there ought to be centralization of effort. The President has now undertaken to carry out these suggestions made in all of these reports by centralizing the work done under the direction of Mr. Ryan.

"I hope to see better results follow from this centralization of power, authority and effort, placing the whole aircraft program in the hands of a man who has been accustomed to do things well and who having been successful in his own affairs—is likely to be successful for the Government."

May 8

Open Hearings on Air Charges Urged

Chairman Chamberlain of the Senate Military Affairs Committee will delegate the task of investigating the aircraft situation to a sub-committee which will do the work without fear or favor.

It is hoped in army circles that the Senate committee will begin by examining Gutzon Borglum, author of the charges against the Aircraft Production Board, and that the hearings will be open to the public. The belief is that the War Department will not object to this procedure, especially as it will be possible to have secret sessions when necessary in the interest of military secrecy.

At present a majority of the committee is believed to favor secret sessions. Senators who favor secrecy say that some of the officers of the United States Army who have expressed a willingness to lay bare what they know of the unfortunate conditions in the aircraft program are not anxious to appear in public.

They feel that publicity would result in reprisals from higher up and might cause efforts to drive them out of the army. The men who are known to be willing to tell the Senate sub-committee what they know are not confined to officers of the reserve force or uniformed experts who have been nominally army men since the United States entered the war, but in many instances they are West Pointers of long service and recognized loyalty.

Suggested for the sub-committee in addition to Senator Reed are Senators Thomas (Col.), Kirby (Ark.), or McKellar (Tenn.), Democrats, and Senators New (Ind.), and Johnson (Cal.), Republicans. Only two of the Democrats will be selected, and it may be that in the end Senator Thomas will feel that he is unable to serve.

May 9

Baker Refuses Court of Inquiry to Officers at This Time

Senator Thomas of Colorado, a member of the Military Affairs Committee, declared in the Senate that, under the Administration's contracts with aeroplane manufacturers it appeared as if there had been "huge profiteering." He urged that the contracts be revoked. The existing system, he said, by which aeroplane producers were able to operate under one another's patents, as selected by the Advisory Committee on Aeronautics, was, in his opinion, "entirely wrong."

This interchangeable, or "cross-line," system of contracts, as it is called, under which aeroplanes have been made for the American Army since the country's entrance into the war, has operated, Senator Thomas said, to the advantage of the big manufacturers, who had been able to establish a monopoly, as they held the principal patents approved by the Advisory Committee.

Secretary Baker announced that he had been appealed to by Major General George O. Squier, Chief of the Signal Corps; Colonel E. A. Deeds, Chief of its Aircraft Equipment Division, and Colonel R. L. Montgomery, Chief of its Aircraft Contract Division, for courts of inquiry in connection with the aircraft situation. The Secretary said he would not at this time grant their applications, because he did not care to parallel the Senate and Department of Justice investigations.

"The War Department," he said, "is anxious to facilitate and expedite in every possible way the inquiries already instituted by the Department of Justice and the Senate committee. A third examination of the same set of facts at the same time might delay the inquiry, and for that reason I shall hold these applications unacted upon for the immediate present."

May 10

What amounted to charges that Gutzon Borglum, the sculptor, sought to use for personal gain the commission given him in January by Resident Wilson to inquire into the aircraft program, were laid before the Senate by Senator Thomas of Colorado. Documents were presented and read into the record which were intended to show that Mr. Borglum, while engaged on the inquiry intrusted to him, was dealing with a manufacturing concern with the purpose of forming an aircraft production company that would receive assistance in getting contracts through Mr. Borglum's reputed standing with the White House. The documents, which included sworn statements, letters and telegrams, come from the files of the Army Intelligence Office.

The story in brief, from the view suggested by the documents presented to the Senate, is that Mr. Borglum became acquainted on a railroad train with Kenyon W. Mix, Jr., whose father is said to be the controlling factor in the Dodge Manufacturing Company of Miskawaka, Ind., and subsequent meetings between them resulted in discus-

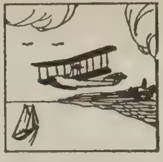
THE NEWS OF THE WEEK



Air Service Institute Organized

The Aero Club of America has been advised of the organization of the Air Service Institute of the United States, which is to be conducted on the lines of the U. S. Naval Institute, which was organized in 1873 and is the leading naval organization in the United States.

The objects of the Air Service Institute of the United States will be the advancement of professional and scientific knowledge in military and naval aeronautics.

Major William Thaw, the dean of American aviators in France, has been selected as president; Major Raoul Lufbery, the other American Ace, as first vice-president.

All the other officers selected as officers of the Institute are well known Army and Navy aviators, as follows:

Col. Charles de F. Chandler, the veteran expert in ballooning; Lieut. Com. U. D. Herbster, U. S. N., who was the third naval aviator to be trained; Major A. R. Christie, U. S. A., one of the veteran Army aviators who served at the Mexican border; Lieut. Col. C. C. Culver, recognized as the leading aero radio expert in the United States; Lieut. Com. Warren G. Child and Lieut. Com. L. H. Maxfield, two other veterans of the Naval Air Service; Major Jack W. Heard, another veteran Army aviator; Capt. F. L. La Guardia, the New York Congressman, who joined the Air Service at the start of the war; Major Cushman A. Rice, of the Army Air Service, veteran of the Spanish-American War; Capt. Thomas A. Baldwin, the veteran balloon expert; Capt. K. G. Pulliam, Jr., U. S. A., and Lieut. C. E. Ruttan, U. S. N. R. F. C.

Twelve more officers are to be selected from the Army and Navy Air Service to make up the Board of Directors

The by-laws of the Institute provide that the officers in charge of the Army and Navy Air Service in the United States and in France shall be elected honorary members.

Following the practice of the U. S. Naval Institute, the Air Service Institute will offer prizes annually for the best essays, which will be on aeronautic subjects, and the annual membership dues will be two dollars.

The essays will be published in the Institute's official organ, which is to be called "Air Power."

The Air Service Institute has temporary offices in the Union Trust Building, Washington, D. C. It will also have offices in France, England and Italy.

The membership of the Institute will consist of regular, life and honorary and associate members. Regular members shall be officers of the Army and Navy Air Service and all civil officers attached to the Air Service. Those who do not come under this class will be associate members.

The officials of the Aero Club of America have extended their hearty co-operation to the Air Service Institute.

Navy Must Quadruple Plane Output

Washington, D. C.—It has been found necessary to quadruple the output of the navy's aeroplane factory at League Island, Philadelphia. This will be accomplished by making the plant an assembling factory for naval aircraft and placing contracts for parts with scores of manufacturers.

The Philadelphia factory reached its maximum of production within eight months from its inauguration, but the order for quadrupling its output requires the placing of large additional contracts with aeroplane parts manufacturers.

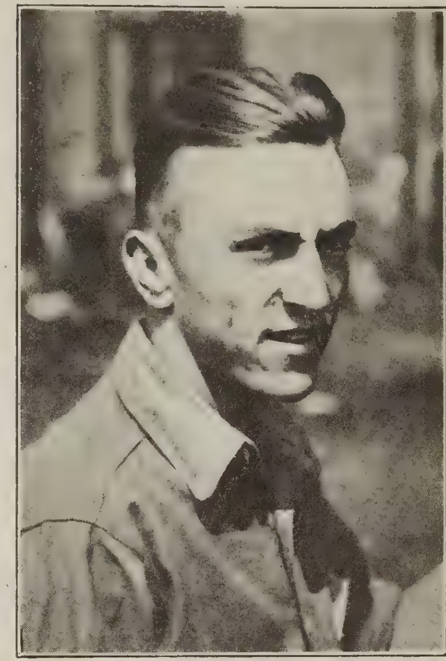
Auto Manufacturers Need War Contracts to Counteract Curtailment Order

Washington—Representatives of the National Automobile Chamber of Commerce, who were in a three-day conference with the War Trade Board, having agreed to a heavy curtailment of pleasure car production, pointed out the necessity of their receiving war contracts for aeroplane engines, ambulance trucks, tanks, tractors, gun carriages, mine anchors, shells and other munitions, in order to keep their organizations intact.

On the committee of manufacturers are W. C. Durant, J. N. Willys, John F. Dodge, W. E. Flanders, C. C. Hanch and Hugh Chalmers. They issued the following statement:

"After a thorough investigation the committee was convinced that the demands of the government, direct and indirect, were very great, and, conceding that these demands should be given unquestioned priority, volunteered all possible assistance and pledged the entire resources of the automobile industry to speeding up the war programme, at the same time keeping in mind its accomplishments, with so little disturbance to general business as possible.

"Until the government requirements are more definitely known, the automobile industry, in addition to the manufacture of aeroplane engines, ambulance trucks, tanks, tractors, gun carriages, mine anchors, shells and other munitions, will apply itself to helping to solve the great problem of transportation, which is directly in its line."



"Eddie" Rickenbacher, the famous automobile record holder, has downed his first German plane

War Inventions Section New Division of General Staff

Washington, May 11.—In order to promptly consider all inventions of mechanical, electrical or chemical nature, the Secretary of War announced that a new division of the General Staff has been created. The announcement states:

"Inventions may be sent by mail or may be submitted in person, accompanied by written descriptions or drawings. They go first to an examining board having technical knowledge of the classes of inventions they handle, whose investigations determine whether the inventions have merit. Those which possess merit are referred to the Advisory Board.

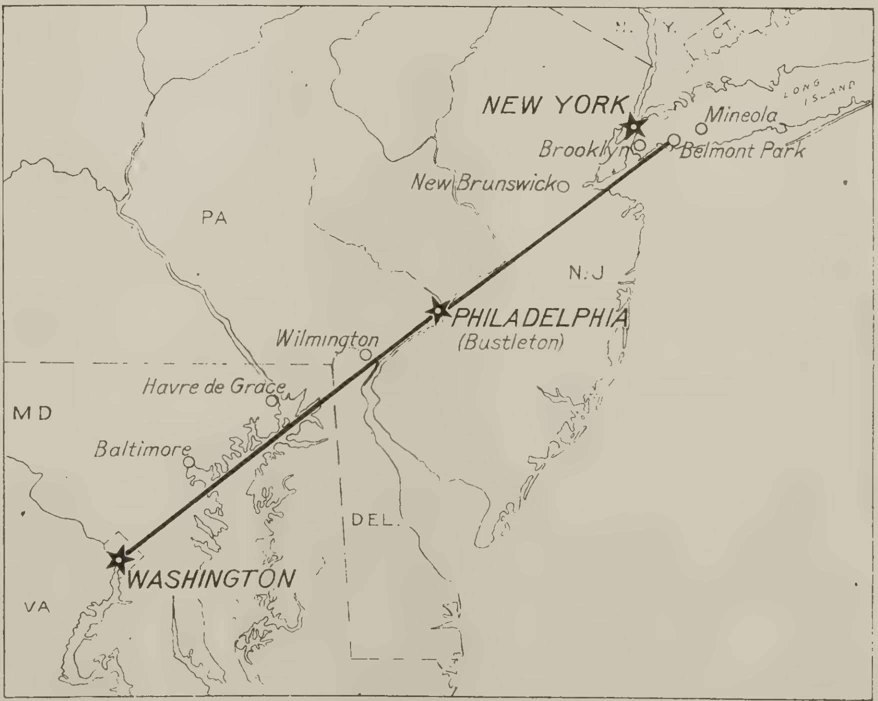
Composing the Advisory Board of present are the following:—

"D. W. Brunton, member of Naval Consulting Board, and chairman War Committee of Technical Societies; Dr. Graham Edgar, member National Research Council; Colonel James W. Furlow, Quartermaster Department, Chief of Motors Division; Colonel J. A. Hornsby, M. C., Chief of Hospital Division, Surgeon General's office; Lieutenant Colonel Morgan L. Brett, Ordnance Department, Engineering branch; Lieutenant Colonel A. Millikan, S. C., Chief, Science and Research Division; Lieutenant Colonel N. H. Slaughter, S. C., Chief of Radio Development section; Major Joseph A. Mauborgne, S. C., Chief, Electrical Engineering section.

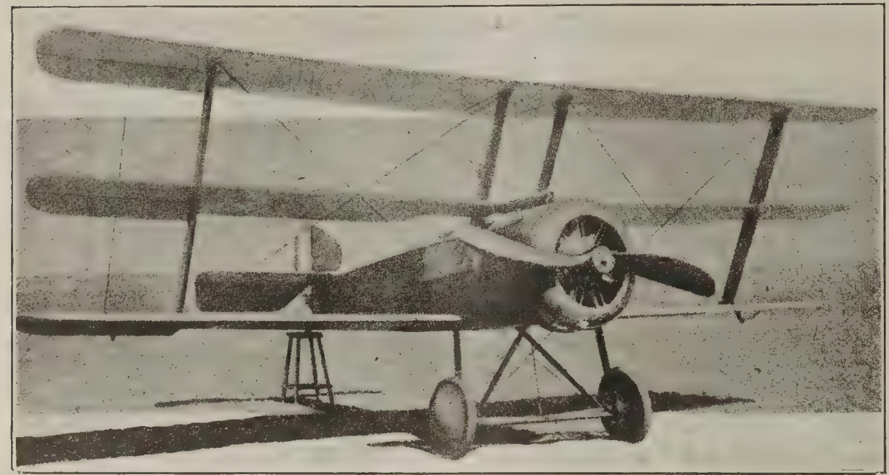
"When completed the Board will have twelve to fifteen members, to cover fully all of the various technical problems which may come before it.

"In testing and developing inventions and in considering problems presented by staff departments, the Advisory Board works in connection with a number of agencies. Among them are the following:—

"Research Council, Bureau of Standards, War Committee of National Technical Societies (this committee consists of two members detailed from each of the ten important technical societies in the United States), laboratories and shops of the staff and supply departments of the army, Patent Office, Aircraft Production Board, all army service schools, C. L. Norton, Massachusetts Institute of Technology, Cambridge, Mass.; Dr. Charles P. Steinmetz, General Eletric Company, Schenectady, N. Y.; A. H. Beyer, chairman Committee on Testing Laboratory, Columbia University, Broadway and 117th street, New York City; R. R. Abbott, metallurgist, Peerless Motor Car Company, Cleveland, Ohio; Dr. John A. Mathews, president Halcomb Steel Company, Syracuse, N. Y.; Knox Taylor, president Taylor-Wharton Iron and Steel Company, High Bridge, N. J.; Howard D. Colman, Baber-Colman Company, Rockford, Ill.; Preston S. Miller, Electrical Testing Laboratories, Eightieth Street and East End Avenue, New York City; Herbert Fisher Moore, University of Illinois, Urbana, Ill.; L. F. Miller, metallurgist, Mitchell Moore Company, No. 1,832 Asylum Avenue, Racine, Wis.; E. J. Okey, the Timken Roller Bearing Company, Canton, Ohio, and Dr. Alee Hrdlicka, cura or, division of physical anthropology, United States National Museum, Washington, D. C."



AERIAL MAIL ROUTES. WASHINGTON-PHILADELPHIA-NEW YORK.



A Sopwith Triplane, photograph of which appeared in a German periodical

Miss Katherine Stinson Postal Air Clerk

Miss Katherine Stinson, the aviatrix, has been sworn in as a postal clerk, and has been assigned the duty of carrying mail from Chicago to New York by aerial mail. She expects to accomplish the flight in eleven hours.

Evan J. David Addresses Harvard Aeronautical Society

Mr. Evan J. David, the business manager of "Flying," addressed the Harvard Aeronautical Society on May 9th on "Aircraft in Warfare." The lecture was well attended, not only by members of the society, but by the Harvard faculty and the student body in general.

With Our Boys "Over There"

Flight Captain James Norman Hall, author and one of the best-known American aviators, is missing after a thrilling battle between three American aeroplanes and four German machines, ten miles inside the German lines. Captain Hall's home is Colfax, Ia.

An Associated Press Dispatch from France dated May 8th declares that the Germans have sent some of their best flyers to the Toul sector, where American aerial forces are operating, with a view of annihilating our airmen. Lieuts. A. J. Coyle, pilot, and Steward B. Board, observer of a photography aeroplane have been decorated with War Crosses for driving off three German Albatross machines, when attacked northwest of Toul, and then continuing on their mission.

Sergeant Frank L. Baylies, of New Bedford, Mass., and in the French Air Service, has brought down his seventh opponent. All his victories have been achieved in the last two months.

An American gunner recently accomplished the feat of bringing down a boche airman with a pot shot from a seventy-five mm. gun. The German had just crossed the lines over Toul. It is rare that artillery brings down an aeroplane over the front lines.

Lieut. A. L. Koyle, pilot, and Lieut. S. B. Bird, observer, were decorated with the Cross of War, according to a news dispatch from the "American Army in Lorraine." They fought three German aeroplanes directly over the front lines in an observation balloon.

Lieut. Gustav H. Kissel has been reported missing by General Pershing. He is the son of Rudolph H. Kissel, a prominent New York banker. Lieutenant Kissel enlisted in the Aviation Section a week after we entered the war and acquired the reputation of being a very skilful airman. He was a member of the Harvard Class of 1917.

A group of American aviators on duty "somewhere in France." On the extreme left front row is John Guy Gilpatric, well known to Aerial Age readers, as a contributor to its columns

Major William Thaw and Paul Frank Baer have again been cited in the "Journal Officiel."

Automobile Club of France Offers Prizes for Kerosene Carburetor

Paris, France—Three prizes of $10,000, $2,000 and $400 are offered by the Aero Club of France for the most satisfactory automobile engines running on kerosene of 810-820 density and with minimum flash point of 35 deg. Cent. in Garnier apparatus. Exacting laboratory and road tests will be applied to ascertain the respective merits of the various contestants.

At the Aviation Fields

Captain Alfred Heurtaux visited Ellington Field, Olcott, Texas, on April 18th, making a detailed inspection of the fields, shops, schools and hangars.

The Willys-Overland building ih Minneapolis, Minn., has been turned into a branch aviation training school for Dunwoody Institute. Aviation mechanics will be taught in the new building under Commander William J. Terhune, formerly in charge of the Key West naval training station. The men will be quartered in the Willys-Oveland warehouse.

The first class of the year passed the Reserve Military Aviator tests at Chaunute Field and have been commissioned second lieutenants. In former times the officers were recommended for commissions here after passing their tests and several weeks later they would be notified from Washington, D. C., that they had been accepted. Under the new method commissions are given at once.

Two aviators, Lieut. Arthur Laverents and C. C. Cotton, from the Naval Reserve aviation training school at Miami, Florida, had a thrilling experience when on a trial spin on May 5th. The two aviators started on a coast patrol flight in a large seaplane. Far out, they were forced to make a landing on account of engine trouble, and the heavy sea began pounding the sturdy seaplane. It was not long before several sharks appeared. The aviators tried to repair their machine, but were unable to do so. To add to their difficulties, one of the pontoons smashed. After drifting all day and all night Sunday, they were rescued by the steamer Sixaola.

Before a crowd of 25,000 people, some of America's foremost champions of track and field, who are now learning the art of flying, performed in spectacular fashion at the field day and athletic meet held at Camp Dick on May 11th.

Fred J. Kelly, former Olympic champion, won the 120 and 220 yard hurdles. Other contestants in the meet were: Harry Babcock, famous Columbia pole vaulter; Nichols, former track captain at the University of California; Charley Harley, of Ohio State; M. J. Hayes, the Princeton sprinter; Charles Stout, Western Intercollegiate Conference Association champion; E. L. Sanders, Illinois University runner; Templeton, Leland Stanford, high jumper; etc., etc.

Under the command of Captain C. F. Betz, the first group of eight hundred men are soon to finish their term of instruction at the Army School for Aerial Photography, at Rochester, New York. Plans are being formulated to give the men practical experience in flight.

New Export Regulations

Washington, D. C., May 12.—In order to further conserve shipping space and tonnage, the War Industries Board, in cooperation with the Food Administration and War Trade Board will require the issuance of shipment licenses on all exports on and after May 15th, including such shipments as already have been licensed for export.

Applications for shipments for the United Kingdom must be made to the British War Mission, Munsey Building, Washington, D. C.; for France, to the French High Commission, 1954 Columbia Road, Washington, N. W.; for Belgium, to the Belgian Commission, Room 202, Council of Defense Building, Washington, D. C. Upon the approval of these applications, they will be forwarded by the commissions to the Bureau of Exports, Washington, D. C.

Applicants must agree not to acquire of manufacture for export articles specified in the application, until licenses are granted for shipment. Food manufacturers and exporters and all "essential" industries fall within the new regulation.

On July, 1918, all licenses granted previous to May 15th, expire.

Colonel Disque to Confer with Chief of Staff

Washington, D. C.—Colonel Brice P. Disque, who has charge of the Spruce Production Division, with offices in the Yeon Building, Seattle, Washington, has been ordered to report to the Chief of Staff, Washington, D. C., for conferences at the War Department. Through Colonel Disque's efficiency and energy, there has been a great increase in the production of spruce, which is used more than any other kind of lumber in aircraft construction, and a large proportion of which is produced in Washington and Oregon.

President Asks Boy Scouts to Take Walnut Census

Washington, D. C.—At the request of President Wilson, the Boy Scouts of America have been asked to take a census of walnut trees in the United States. The President's letter says in part: "In order to carry out the programme of the War Department it is of the utmost importance that large quantities of black walnut lumber should be secured for its use. Black walnut is used by the Ordnance Department for the manufacture of gun stocks, and by the Signal Corps for the manufacture of propellers for battle and bombing aeroplanes."

Augustus Post Lecturing Extensively

Mr. Augustus Post, honorary secretary of the Aerial League of America, is continuing his educational lecture work on aeronautics. Recently he has spoken before the Contemporary Club of Philadelphia, the Barbadoes Club, Emerson High School and various other organizations. Mr. Post has also spoken on the Sub-Treasury steps, Hotel Plaza, and numerous other places in behalf of the Liberty Loan.

German Aircraft Weakened By Improper Materials

Shortage of spruce is compelling Germany to substitute steel and aluminum, with the result that many aviators are being lost through accidents. It is said that steel cannot withstand the sudden strains of rapid manœuvres, and one correspondent states that Allied aviators do not always employ their machine guns in vanquishing their adversaries, merely manœuvring in such a manner as to compel the Germans to make a quick "corkscrew" turn. Unable to endure the sudden wrench, the steel braces supporting the aluminum wings sometimes snap, and the aviator is downed.

British Air Forces Memorandum Explains Terms of Service

Every person enlisted in the Royal Air Force is liable for duty afloat or ashore, at any station at home or abroad, and may be detailed to any branch of the service; and may be called upon, if medically fit, to go into the air in airships, aeroplanes, seaplanes, kite balloons or any type of aircraft. The selection of a man for service does not imply that he will be trained as a pilot. The chief requirements for candidates to the Cadet Wing are: Age, over 17 years 11 months, and under 30 years. Height, less than 6 feet 1 inch. Weight, less than 182 pounds.

The pay is as follows: Upon enlistment and during preliminary training, $.36. At school of aeronautics, $1.96 per day plus $.96 per day on each day requiring flights. Graduated flying cadets, $2.40 per day plus $.96 per day on each day requiring flights.

Fonck Advises American Fliers

In an interview with a New York "Times" reporter recently, Lieutenant Fonck, the famous French ace who has downed thirty-three German aeroplanes, stated that for Fonck four things count as an air fighter's assets: Flying ability, accuracy of shooting, automatic swiftness of decision and coolness. Unlike many great fliers—Lufbery and Guynemer, for example—he does not put shooting first.

"Manoeuvring your opponent is the chief thing," he said. "Directly I engage an enemy I can judge what line to take. You can tell from the outset just what quality of pilot is opposed to you, and must act accordingly. I have never fought Richthofen, but I am certain I should know in ten seconds that I was at grips with him if we met, and he would know, too. The way a pilot handles his machine is an unfailing indication of his calibre.

"Don't believe the stories about the most successful airmen diving from a great height and abandoning the struggle if the enemy is missed. That may have been true once, but at present such tactics are impossible You must fight and fight close. The victorious aviator is the man who knows best how to handle his machine so as to meet changing situations most adequately, and who has the quickness of decision to translate that ability at once into action."

"But against heavy odds," the reporter said. "Surely you are at a disadvantage when several attack you at once."

Lieut. Richard F. Harris, one of the editors of "Tale Spins," published by the cadets and officers at Ellington Field, Houston, Texas

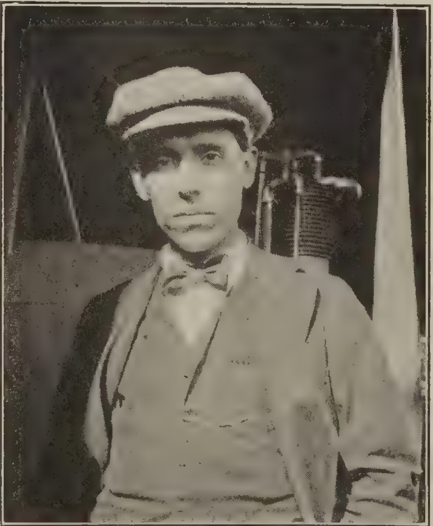
"Not in the least," he replied. "You just give ground and manoeuvre them"—he emphasized the word—"and then go for the one who is in the worst position."

"The greatest number I ever fought alone was seven, at Verdun, I dodged around until I got my opportunity, and then went for one and downed him. A moment or two later I got another and gave a third more than he liked, so that he made off. That left four. I dived at one, and, although I missed him, came so close"—Fonck begins firing at 150 yards and continues until he is five yards distant, when he swerves for an instant to avoid collision—"that he decided to quit also. When I wheeled to tackle the rest they were streaks on the horizon."

Asked if he had any advice to give to the American airmen, Lieut. Fronck replied:

"Avoid all excess and train as for a prizefight. From the practical point of view the best thing is to get attached to a first-class French group. We know the game, and a young pilot cannot do better than fly with a group in which there is at least one crack. The latter not only gives the confidence which is essential to novices, but shows them how, and is there to disengage them from awkward positions.

"Secondly, tell them to learn their machine and engine thoroughly. Ninety per cent of aviators are forced to trust their lives to mechanics for tuning up. That is not good enough for me. Without boasting, I may say I can take any machine of our group, and in a week it will be the best of the lot—not because I am specially clever, but because I know the whole outfit thoroughly. And it is worth learning, because my life depends on it."



E. V. Bellanca, the inventor and designer of the Bellanca Aeroplane, and the Bellanca patented turnbuckle

The Effects of High Flying

I have found the effect of high, *i. e.*, rarefied, air to be felt slightly at about 10,000 feet, increasing with the altitude. Breathing becomes affected, respiration shorter and quicker, there is a curious oppressive sensation and a bulging feeling in the head until the height of about 20,000 feet is reached. I am told by a medical friend who has made rather a study of the subject that there is always a risk of a sudden collapse, and oxygen should be used whether the aviator feels fit or not. Of course, the effect felt varies considerably with individuals, and with the state of one's health. About 18 months ago I suffered slightly with my heart, and found I could not get very high without feeling giddy, and after returning from a flight to 12,000 feet I had palpitation, which lasted until the following day. In consequence I had to abandon high flying until treatment got me fit again. This year I have made a number of high flights and have felt no ill effects whatsoever; in fact, I find the more one gets accustomed to going up high the less the effects are felt. I am told that this also is the case in mountaineering. I can remember the unpleasantness of my first flight to 15,000 feet. It was very marked, especially the pain experienced in the drum of the ears on descending.

The fact that a flight now to 21,000 or 22,000 feet does not have so much effect I put down entirely to acclimatization. I use oxygen as a precaution when ascending beyond 20,000 feet, for the previously mentioned reason. A small bottle is carried, fitted with a special reducing valve, which is fixed in the fuselage within easy reach of the hand. No special regulation is required, as it is set to pass only the necessary amount of gas into the face mask which acts as a mixing chamber, with its inlet and outer air valve. The apparatus weighs 16 pounds, and contains sufficient oxygen for one hour's continuous use. After reaching 20,000 feet I find it is only necessary to use the oxygen intermittently, and accordingly I simply hold the mask, after turning on the gas, over the mouth and nose and take a few breaths of it, perhaps every half minute. The effect to me is remarkable; most of the oppressing feeling vanishes, and, excepting for the unpleasant bulging feeling of the head, which you experience with a bad cold, the sensation is one of suddenly being again at ground level.

The only after-effects upon landing from these high altitudes are that you seem to acquire a pretty good thirst, due, I suppose, to the use of oxygen. If the speed of climb continues to improve at the rate it has for the past three years, it looks as though aviators will become subject to what is known as "Caison Disease," due, I am told, to the sudden reduction in atmospheric pressure, such as divers are subjected to when they come to the surface from a great depth, owing to the nitrogen, which has been absorbed by the system, in proportion to the atmospheric density, forcing itself too rapidly at any lower pressure from the system.—Abstract from a paper before the Aeronautical Society of Great Britain by Capt. B. C. Hucks.

New Aircraft Company in New York City

Aeroplanes are to be made at City Island, New York City, in the Robert Jacob shipyards, where some of the American cup defenders were turned out. Plans were filed recently with the Building Department for the new factory, which is to cost $210,000, from plans by the Louis P. Fluhrer Company. It will be one story, 60x200, of reinforced concrete.

With "Our Boys" Abroad

Sergeant Vernon Booth, Jr., of New York, a member of the American Flying Corps in France, married Miss Ethel Forgan, daughter of David R. Forgan, a Chicago financier, in Paris on April 27th. Sergeant Booth recently brought down his second German aeroplane and as a reward, a ten day's leave was given him to enable him to get married.

Lieutenant Ely, a member of the Lafayette Escadrille, a native of Chicago, Illinois, died from injuries received in an aeroplane accident in France.

The French Government has awarded the War Cross to Sergeant David E. Putnam of Brookline, Mass., a member of French Escadrille, No. 156; William A. Wellman of Cambridge, Mass., of Escadrille No. 87, and Phelps Collins of Detroit, a member of the Lafayette Escadrille.

Collins was killed on March 13th in an aerial combat. Putnam, Wellman, and Collins enlisted in the Foreign Legion early in the war and fought in the trenches for a long time before joining the aviation service.

The AIRCRAFT TRADE REVIEW
N. E. J.

Government War Finance Corporation Organized

President Wilson has named the four directors of the War Finance Corporation, who will control the $500,000,000 which has been appropriated for the purpose of aiding in the financing of essential war industries. They are: W. P. G. Harding, Governor of the Federal Reserve Board; Allen B. Forbes, New York; Eugene Meyer, New York, and Angus W. McLean, Wilmington, Delaware.

The corporation will start with a capital stock of $500,000,000 and has authority to issue $3,000,000,000 in bonds with which to finance its operations. Loans may be made to banks amounting to 75 per cent of the face value of loans made by banks to any business "whose operation shall be necessary or contributory to the prosecution of the war."

Direct loans to essential industries may be made to essential business, if the directors of the War Finance Corporation decide that such an advance is necessary. In such cases 125 per cent collateral is required, but the loan is limited to **12½ per cent of the corporation's** total capital stock and outstanding bonds. The War Finance Corporation has quarters in the Treasury Building, Washington, D. C.

An important part of the corporation is its Capital Issues Committee, consisting of seven men, which have authority to pass on new issues of stock amounting to $100,000 or more. While the committee has not the power to directly prevent the issuance of more than that amount of stock by any corporation, it can, with the co-operation of the Federal Reserve Board, make it impossible to sell an issue of stock amounting to $100,000 or more, without its approval.

Universal Machinery Company Building New Plant

Milwaukee, Wis.—The Universal Machinery Co., manufacturer of lathes, boring mills, drill presses, etc., is planning to build a complete new plant in West Allis, the manufacturing suburb of Milwaukee. The first units to be built will be a machine shop, foundry, power house and auxiliary structures. J. E. Purdy is secretary and treasurer of the company.

Stewart-Warner Employees Buy Liberty Bonds

Chicago — The Stewart-Warner Speedometer Corporation has subscribed for $201,400 worth of Liberty Bonds. Within four days after the opening of the campaign, 1,637 employees had signed subscriptions. These figures are for the Chicago factory only, and does not include the subscriptions of the Beloit plant, or of the 60 branch offices and service stations.

Splitdorf Magneto Gets Another Government Contract

Washington, D. C.—The Splitdorf Electrical Co., of Newark, N. J., has been awarded a contract by the War Department for magneto parts. They are the manufacturers of the famous "Dixie" magnetos.

France Protects Gasoline Supply

Paris, France.—All gasoline used by the French army is now being tinted red, in order to prevent its getting into civilian hands by illegal means. A product has been found which will give it this distinctive color without injuring its qualities. It has been found where this check on the supply has been applied, that there has been a reduction in the average consumption of gasoline, indicating that no inconsiderable quantity had previously found its way into improper hands.

For a considerable time, gasoline has only been supplied to those who have absolute need for a car and who were expected to use it for a specified purpose.

Pleasure Car Output to be Curtailed 75 Per Cent

Washington, D. C.—The War Industries Board has decided on a 75 per cent curtailment of the production of passenger automobiles. Piano manufacturers have already been ordered to reduce their output by 30 per cent. The release of the facilities of both of these industries offers an opportunity for increased aeroplane production.

Figures On New Curtiss Factory

Photographs appearing in British aircraft papers of the new Curtiss aeroplane factory in Buffalo, which is nearing completion, give an indication of the enormous size of the plant. The building is stated to be half again as long as the Hamburg-American liner Vaterland. In its construction 5,800 tons of steel and 7,000,000 board feet of lumber were required. Nearly 3,000 men were at work at one time in the erection of the building and the whole contract price was in the neighborhood of $5,000,000.

Lawson Aircraft Tested

The latest aeroplane to be turned out from the Lawson aircraft factory at Green Bay, Wisconsin, was recently tested by Mr. Lawson and George Pufflea. Six flights were made, and the machine remained in the air for two hours.

Walnut Lumber Needed for Propellers

Washington, D. C.—In a circular letter to manufacturers of veneer, Major E. A. Shepherd, of the Ordnance Department, has requested that they refrain from manufacturing veneer from walnut lumber other than butts, crotches or figured material, none of which is suitable for stocks or propellers. This material is urgently needed by the Government.

Personal Paragraphs

Donald Anthony has resigned as manager of the Baltimore branch of the Locomobile Co., to join the Aviation Section of the Signal Corps.

J. V. Thomas has been promoted to the position of sales manager of the B. F. Stearns Co., of Cleveland. The Stearns Co. is making Rolls-Royce motor parts.

Gasoline Production Increased One-Third In 1917

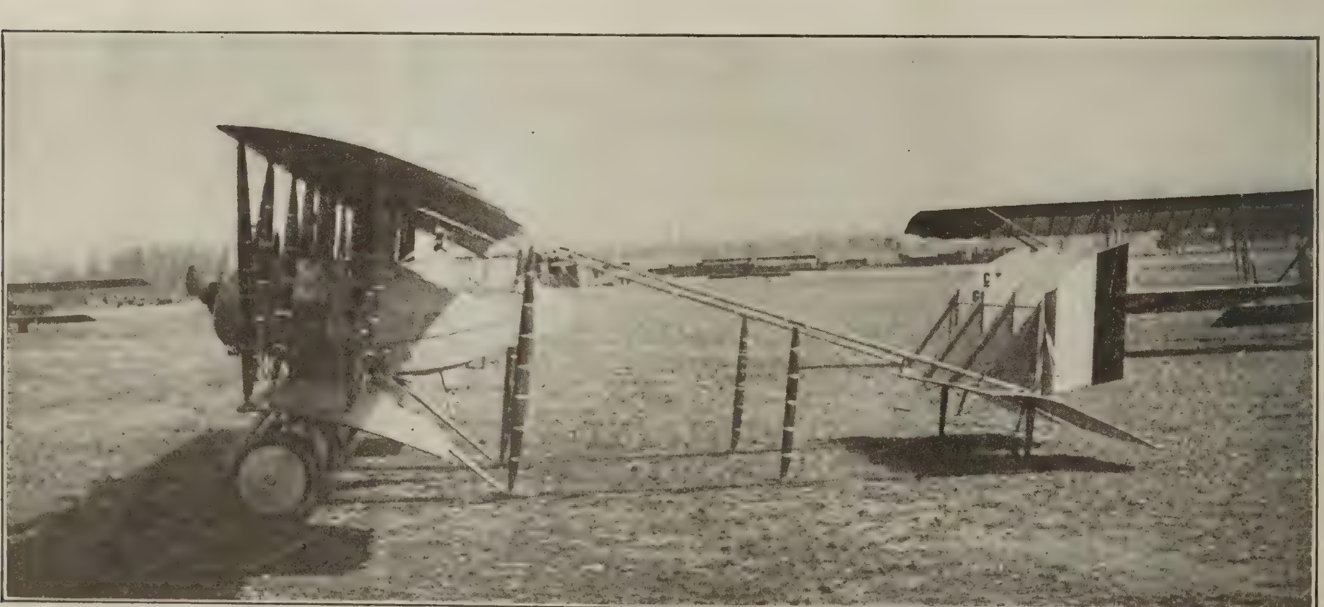
Washington, D. C.—During 1917 the production of gasoline increased 32 per cent, or nearly 2,000,000 per day more than in 1917. The total production for the entire year was 2,729,712,033 gallons, or an increase of 670,831,437 gallons. The production of kerosene increased 7½ per cent and that of crude oil 22 per cent.

Willys-Overland Increasing Output

Toledo, O.—The Willys-Overland Company will increase its working force from 12,000 to 15,000 men. During March, says *Automotive Industries,* the company produced and shipped 832 Curtiss training aeroplane engines.

Bosch Company Reorganized

The personnel of the Bosch Magneto Co. has been completely reorganized and, under Government supervision, plans a considerable expansion of its magneto business. The new officers are: President, Joseph H. Bower, of New York; Vice-president, Christian Girl, of Cleveland; treasurer, George McDonald, of New York;



The Caudron type G used extensively for elementary training in the French Air Service. Note the landing skid extending from the wheel to the tail skid (French Official Photo)

Scene at one of the French flying fields, with some of the elementary Caudron training machines in evidence (French Official Photo)

secretary, William G. Fitzpatrick, of Detroit; assistant treasurer, A. D. Altree, of New York; general manager, A. T. Murray, of Allentown, Pa.

By the induction of these officers, greatly increased output may be expected. At present 800 men are working at the Springfield plant, and only a small proportion of its output is being utilized for Government purposes.

Tire Manufacturers Raise Prices

Washington, D. C.—Owing to the rising cost of cotton fabrics and labor and the expected shortage of crude rubber, due to the new regulation of the Shipping Board, which cuts down the imports of crude rubber by 50 per cent, there has been a general advance in the cost of tire prices on the part of all the large manufacturers of tires, amounting to at least 10 per cent.

Great Lakes Rubber Co. Organized

Milwaukee, Wis.—A rubber manufacturing company has been organized by Donald C. Barbee, general manager of the Badger Belt & Rubber Co. with a capital stock of $100,000. Five acres of land have been purchased in Cudahy, a suburb of Milwaukee, and the first unit of the plant will provide 45,000 feet of floor space. The new company is to be known as the Great Lakes Rubber Co.

Dividends Declared

The Standard Parts Co. has declared a regular quarterly dividend of 1½ per cent on the common stock, payable May 15 to stock of record April 30.

The Westinghouse Electric & Mfg. Co. has declared a dividend of 1¾ per cent (87½ cents per share) on the common stock for the quarter ending March 31. This will be paid on April 30 to holders of record April 4.

The Stewart-Warner Speedometer Corp, has declared a quarterly dividend of 1½ per cent payable May 15 to holders of record April 4.

The Fisher Body Works has declared a regular quarterly dividend of 1¾ per cent, payable May 1 to stock of record April 20. The Fisher Body Works has contracts with the Signal Corps for aeroplane parts.

Detroit Labor Situation Acute

Detroit, Mich.—The labor situation in Detroit is becoming serious. The present shortage consists of 20,000 men, and it is expected to grow to 35,000 within a short time. The great demand has caused manufacturers to advertise in the daily papers. Instead of improving matters, this increased the ranks of "floaters" who are attracted by the higher wages promised in the advertising.

As a result of the plea of a representative of the Detroit Board of Commerce in Washington, Government relief is expected, in the establishment of a Federal Employment bureau in Detroit.

Owing to the transportation situation during the winter, the Ordnance Department has concentrated its contracts with firms along the eastern coast. These, however, are now working near capacity, and hence Detroit, with its great facilities, is expected to receive a larger share of Ordnance Department work. This makes the labor situation more important.

Alexandria Aircraft Corporation

The Briggs Aeroplane Company, on and after May 15th, will be known as the Alexandria Aircraft Corporation. Mr. A. W. Briggs, general manager, has resigned and will use his name in another enterprise.

The Aircraft Industry and the Liberty Loan

The employees of the Brooklyn plant of the Doehler Die-Casting Co. subscribed $56,000 to the Third Liberty Loan.

AERIAL AGE merited a loan flag with nine stars—90 per cent of its personnel having subscribed to the Third Liberty Loan.

The 1,482 men and women workers of the Sprague Electric Works of General Electric Co. had a 100 per cent record, and their subscriptions totalled $116,850.

Navigation Instruments for Aeroplanes Costly

The Signal Corps has issued a detailed statement, pointing out the expense and problems which have been met, in the production of indicating and navigation instruments for aeroplanes. In addition to navigation instruments, actual combat planes, such as observing, photographing, bombing and fighting planes, require many other complicated and expensive instruments.

Among them are machine guns, gun mounts, synchronizers, bomb racks, bomb-dropping devices, bomb sights, radio, photographic, and oxygen apparatus, electrically heated clothing, lights, and flares. The cost of such additional accessories would bring the total cost of equipment for a plane to several thousand dollars each, depending upon the type of plane.

All these instruments must be ready for installation on the aeroplanes as soon as they are assembled, for no plane is complete without them. In some instances, particularly for the two seaters and the heavy bombing machines, 2 and even 3 instruments of each sort are necessary, totalling sometimes as many as 23, but for ordinary work only about 9 of them are needed. The average cost of a set of navigation instruments for a single plane is $350.

The Signal Corps is purchasing practically all the purely navigating instruments and selling them at cost to the manufacturers of the aeroplanes as they are needed to meet the actual output of planes. This provides one purchasing center and prevents the various airplane companies and the Government from competing against one another, creating disorder and confusion among the instrument manufacturers. At the same time it enables the Signal Corps to keep the supply of instruments adequate for the demands of the aeroplane builders, relieving them from this work, and it also affords standard equipment and interchangeability.

The various instruments developed by the Signal Corps include:

The tachometer, or revolution counter, which indicates the speed at which the motor is running. This instrument is being manufactured by three large firms, and quantity production has been reached.

The air speed indicator, which shows the speed of the aeroplane in relation to the air, has been standardized, but the statement gives no production figures.

Three types of altimeters have been developed, recording altitudes of up to 20,000, 25,000 and 30,000 feet respectively. Quantity production has been reached.

A successful aeroplane compass has been perfected after much experiment. One company is producing 200 a week.

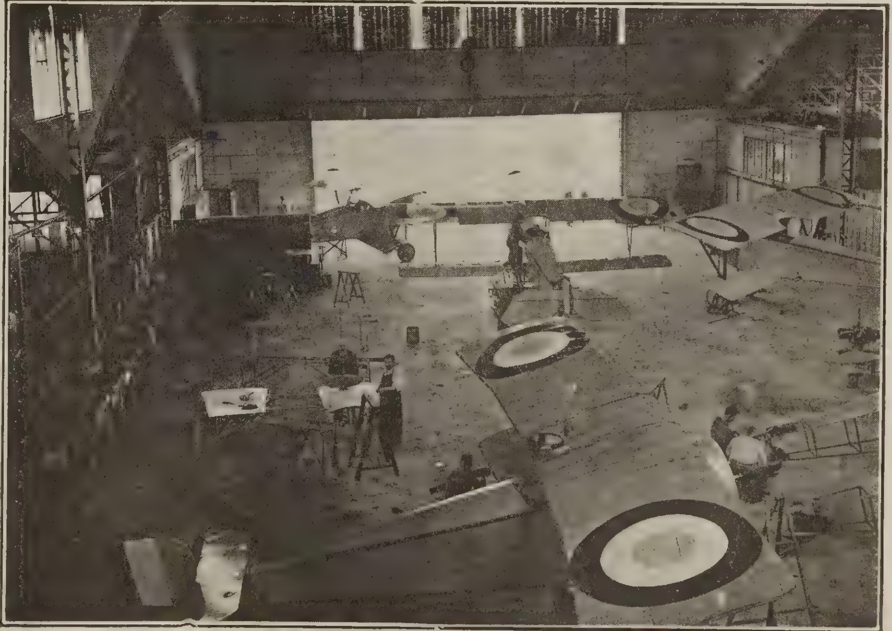
A standardized aeroplane clock was easily adapted from previously existing automobile clocks.

Standard specifications have been issued for pressure gauges for showing the gasoline pressure and oil pressure. They are being produced in quantities.

Two companies are manufacturing radiator thermometers, which form a fairly reliable criterion as to the condition of the motor and its cooling system.

Development work is still under way with a view to designing a reliable banking indicator, upon which much of the accuracy of bomb dropping depends.

An improvement has been made on the Aldis sight, which is used for sighting machine guns firing through the propeller, which makes the Signal Corps model superior to the popular English model.



Final assembly in a French aircraft factory of training and pursuit machines (French Official Photo)

WOODWORKING MACHINERY IN AEROPLANE CONSTRUCTION

THE building of aircraft is, of course, divided into two sections, the one being concerned with the production of the engine, and the other with the machine itself.

The woodworking departments are, obviously, just as important as the machine shops, and to those engaged therein probably more interesting. The work in this department has to be accurate, and special knowledge is also necessary in cutting up the material so that the grain of the timber is arranged in the finished product to give maximum strength.

The timber used in aircraft framework is chiefly ash and silver spruce. The ash trees are sent to the sawmills of our aircraft manufacturers in lengths varying from 16 feet to 18 feet, where they are there cut up into planks varying from 1½ inches to 3 inches in thickness, by means of a powerful log-sawing machine, arranged with the saw working horizontally.

The planks are then taken to the drying shed, and stacked or skidded, so that the air can freely circulate around and absorb the moisture. The old practice of allowing timber about eighteen months to season has been cut down to a much less number in weeks, as the demand is overtaking the supply, and artificial means are necessarily adopted to dry it quickly.

One system is to put the ash into a steam-heated drying room for a period of three to six weeks, at a temperature of 70° F., while another system, known as the Erith, is employed, which takes approximately seven days, but is much more expensive and elaborate.

The silver spruce is usually supplied cut up into planks varying from 15 feet to 40 feet in length, from 12 inches to 14 inches in width, and from 3 inches to 6 inches in thickness. These planks are also skidded in drying sheds for about six weeks, as it is of the utmost importance that the material should be thoroughly dry.

The first operation is to cut up the planks to the required lengths for the various units, by means of a cross-cut sawing machine, or pendulum swing saw, these machines being generally installed at one end of the drying shed for convenience, so that the pieces cut can be quickly passed on to the main joinery and the scrap ends thrown out.

In the main joinery shop the pieces are ripped up by means of powerful circular saws to the dimensions required in forming the units used in the building up of the framework, such as the longerons, side frames, struts, spars, ribs, etc. These units are then stacked up and allowed to remain so for a period of six weeks, in order that they may be thoroughly seasoned before any further machining is carried out. Should a piece pass on without being properly dried, the chances are it will warp, and when this takes place it is at once scrapped by the inspector.

The next operation constitutes the commencement of the real machining, the parts being passed through the planing and thicknessing machines, one of which is illustrated in Fig. 1.

The practice is to utilize one or two sizes of these planers, using the small machines for the light and thin work and the larger machines for the heavier work. The machine illustrated is a panel planing and thicknessing machine, and is designed to take timber from 7 inches to 1/16 inch thick. The frame is composed of iron castings, rigidly connected by several massive cross ties, and with the exception of the countershaft, which drives both the cutter head and the feed motion, the machine is entirely self-contained. The table is raised or lowered by power, the operating lever being conveniently placed on the right of the feeding-in end, a safety stop being provided to throw out the power feed when the table reaches its topmost position. The hand wheel on the left provides a fine hand adjustment. The cutter spindle is ground true, and revolves in substantial phosphor bronze ring oiling bearings. Two knives are usually carried to plane with a shear cut, and are set to project slightly over the lips of the cutter head. The pressures before and after the cutter head are so arranged that very short pieces of timber can be fed through the machine. One important feature is the variable feed gear, which gives any rate of feed from 12 feet to 60 feet per minute, the changes being effected by turning the hand wheel seen to the right of the feeding-in end. The feed gear is driven from the countershaft that drives the cutter head, and consists of two expanding cones with a heavy V felt running between them. The feed motion is instantly started or stopped by the lever at the left-hand side of the feeding-in end, which actuates a belt tightener, also shown on the same side of the machine. The feed rolls are four in number—two above and two below the bed—and are driven by enclosed machine cut gearing. When the timber is planed, it is subjected to the most careful inspection, and any piece with resin pockets, knots, or other defects is rejected.

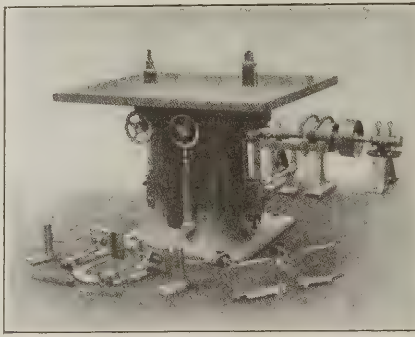


Fig. 2—Double spindle circular moulder

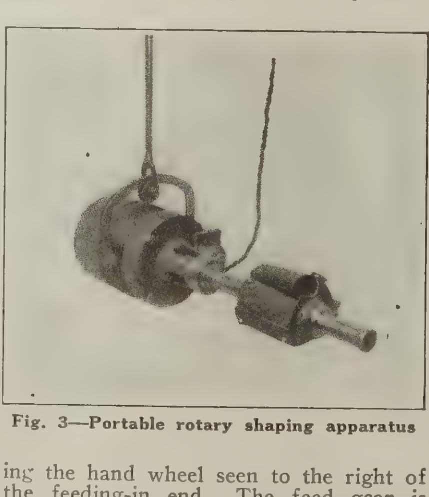

Fig. 3—Portable rotary shaping apparatus

The next machining operation is carried out on the vertical spindle circular moulding machines, which are equipped with one and two spindles.

The double-spindle machines predominate, owing to the fact that they are in general more useful than the single spindle, and the timber can be more conveniently worked when taking the grain of the material into consideration, as the spindles revolve in opposite directions.

Fig. 2 illustrates a double-spindle circular moulder, suitable for working timber up to 4 inches deep. The frame on which the cutter spindles are mounted is a single casting of substantial design and great rigidity. Each spindle is arranged to rise and fall independently by means of the hand wheels shown on the front of the machine. The ends of the spindles are made removable, so that cutter holders of different forms to suit various kinds of work can be used. The table is 4 feet long by 3 feet wide, and is, of course, machined true on the top; the spindles are 24 inches apart.

The wing and tail plane spars, which are made from spruce, have to be recessed or moulded on the sides to form an "I" girder section. This recessing work is rapidly accomplished by having a cutter of the correct form bolted on to the cutter block. The spars are fed by hand past the cutter, the exact depth of the recess being obtained by an adjustable fence or guide.

In some cases the operator prefers to work this without using the fence, and obtains the correct depth of recess by having the cutter held in a slotted cutter spindle end, which is screwed on to the main spindle. The work is fed gradually in until it touches the spindle which acts as a guide, the cutter standing out the required distance for the depth of the recess. When the recess is rather wide, it is the usual practice to cut half the width out with one spindle, and the other half with the second spindle. In the single-spindle moulding machines the cutter spindle is arranged to run in either direction, so that the recessing can be done to suit the grain of the timber.

The wing spars average about 20 feet in length, 2¼ inches wide, and 4 inches deep. They are recessed on both sides, the recessing being intermittent, because parts must be left solid where the bolt holes and the steel fittings are located.

The tail plane has a thinner section and is recessed on one side only, the recesses being also intermittent. These spars are then glued back to back, and finally form an "I" girder section. The main plane struts are also moulded on these machines in the shape of an oval section, the ends being slightly tapered by hand, or by means of a portable rotary shaping apparatus, as shown in Fig. 3. This is a handy and portable tool for shaping irregular wood surfaces, and is used to great advantage on such work as propellers. The apparatus is directly coupled to a high-speed motor of ½ b.h.p. The cutting tool consists of a solid circular cutter, about 3 inches in diameter, operating with a shear action; it is mounted on a spindle running in self-aligning double row ball bearings, carried in a gun-metal and steel casing, handles being formed on each end of the casing for controlling and supporting the apparatus. Provision is made for regulating the amount of projection of the cutter, as required for heavy or light cuts, or by the curvature of the surface to be shaped. The funnel-shaped opening on the top of the casing allows the chippings to be discharged. The shaper alone only weighs 12 pounds, but it is necessary to balance the weight of the motor. This balancing gear consists of a swivelling yoke, hinged to the motor as illustrated, and suspended from a runway above by a double rope, which passes over pulleys on an overhead trolley, and is attached to the balance weight. If electric current is not available, the apparatus can be supplied with a flexible shaft drive of simple construction. It consists of a driving head mounted on a pillar, the head being arranged to swivel to give additional range. The head is driven from a countershaft, and the spindle end is connected to the flexible shaft, which is usually about 10 feet long. The balancing gear and runway are also provided.

The final machining operation is the drilling of the bolt holes in the spars and longerons. Gigs are used, so that no marking out is necessary, and all the holes, of course, are bored accurately, so that each piece is interchangeable.

The rib centers are cut out and built up from three-ply ash, with spruce cappings.

All the machined parts are now taken to the unit assembling department, where the fuselage, center planes, main planes, tail planes, ailerons, and elevators are assembled in specially designed jigs. The metal fittings are fixed and the tension wires put on and just tightened sufficiently for these units to be tested for alignment, etc. The tightening up of the tension wires is a delicate operation, and requires considerable skill as well as experience, as of course each wire must be at the correct tension.

The complete units being inspected and all adjustments necessary made, they are then passed on to the paint shop to be varnished, and when dry are returned to the former department, where the planes, ailerons, and elevators are covered with fabric—usually pure linen. The linen is cut up to the required lengths and shape and is sewn on by women workers, who are now thoroughly accomplished and do very good work.

All these parts are then taken to a special department, where the fabric is treated with "dope." This liquid is painted on with a brush by hand, and the linen is given several coats. The time allowed between each coat is some hours. The idea of treating the fabric in this way is to tighten it up and give it a coating or skin that will protect it from the weather. In this department the temperature is always maintained at 70° for drying purposes, and to protect the workers against the obnoxious fumes from the painting operation, the air is changed thirty-six times per hour by mechanical means. The fumes, being heavier than the air, fall to the ground.

When the fuselage is assembled and trued up, it is carefully inspected and the alignment tested in every way. This is carried out by means of a central line, as the slightest deviation makes itself felt in the flying of the machine. This alignment test is carried out by one of our well-known manufacturers in the following manner: The fuselage or body is set up so that the part of the longerons just above the engine bed is perfectly level, lengthwise and crosswise, as they are at this point parallel to the center line of the engine. At any section in the length the body should be rectangular, and if not, adjustments are made by the cross bracing wires. The tubular stern post should be perfectly vertical with the body in the above position, and is tested by means of a plumb line. The test for seeing whether the body is perfectly symmetrical for the whole of its length is accomplished in the following manner: A straight-edge about 5 feet or 6 feet long, is set across the front body struts, and two points marked off equidistant from the center line of the body. From these points, measurements are taken to the center of the stern post, and if these distances differ, the horizontal bracing wires are adjusted until they are equal. Another test is to place a straight round bar through the tubular tail socket at the rear of the body, and mark off two points equidistant from the center line. The distance from these points to those on the straight-edge at the front should be equal. If not, adjustments are made by the cross bracing wires.

Final Erection

We now come to the final erecting of the machine. The body is mounted on its carriage, the main planes are then fitted to the body, and the dihedral angle tested. The wings of an aeroplane are said to be at a dihedral angle when both right and left wings are upwardly or downwardly inclined to a horizontal transverse line. The angle is measured by the inclination of each wing to the horizontal. If the inclination is upward, the angle is said to be positive; if downward, negative.

The angle of incidence is the angle a wing makes with the direction of its motion relatively to the air. The angle is usually measured between the chord of the wing and the direction of motion. When adjusting the main planes, the incidence, stagger, and dihedral will have to be constantly checked, one against the other, for any alteration to one may affect the adjustment of the others. The stagger of the planes means the distance the leading edge of the upper plane should project in front of the leading edge of the lower plane throughout the whole length. When these adjustments have been made and checked, the leading edges of the main planes must be squared with the center line of the body. The tail plane with its elevators is now fixed and adjusted, so that the leading edge is square with the center line of the machine and parallel to the top body rail. The rudder is placed in position, and should be vertical and parallel to the line of flight.

The controlling organs of the aeroplanes are, of course, the rudder, the elevators in the tail plane, and the ailerons or balancing flaps in the main planes. All these are controlled by means of levers and connecting cables from the cockpits, or pilot seats. When these controlling levers are set in their vertical positions, the various organs by which the machine is operated should, of course, all be neutral positions.

When the final aligning of the machine has been completed, it is carefully checked at all points, and note taken that all turnbuckles are locked and have a secure hold on the barrels. Special attention is given to see that all turnbuckles on the control cables are locked, and all split pins which lock the nuts on the bolts are opened out.

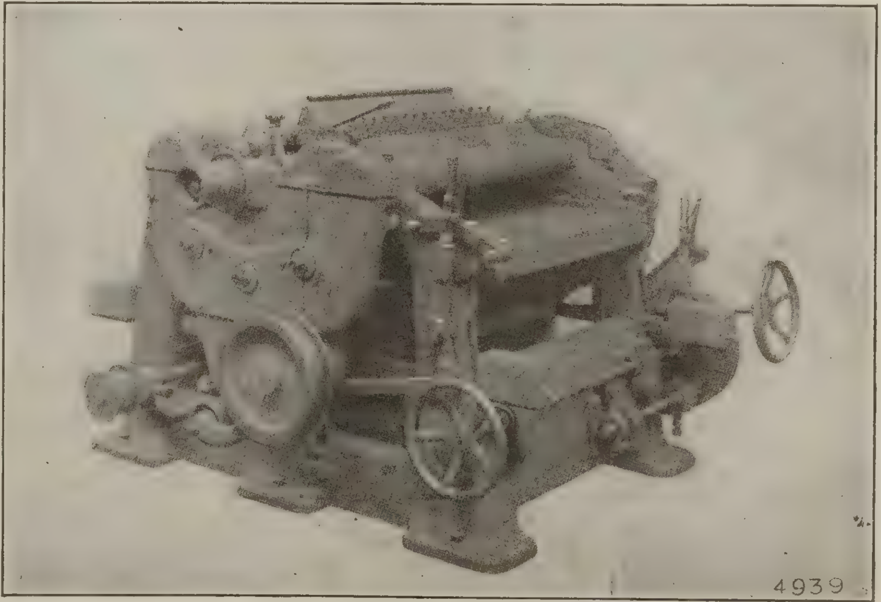

Fig. 1—Panel planing and thicknessing machine

THE FRIEDRICHSHAFEN 450 H. P. GOTHA II FIGHTING AND BOMBING BIPLANE[*]

THE Fliegenblau Friedrichshafen Gesselshaft are well known as the constructors of the Zeppelins, but it is not generally known that they have also turned out many single- and twin-engined seaplanes, for which their works, on the shore of Lake Constance, are well adapted. They are also responsible for a large output of scouts and bombing machines, including the Gotha, type II., more especially of late, since the construction of Zeppelins has recently been considerably moderated for reasons that are only too obvious.

M. Lagorgette, to whom we are indebted for details of the F. F. Gotha II. captured on the French front, states that this machine is merely a modification of their big seaplane, which is not quite correct, as it is evidently based more on the lines of the Erfurt Gotha. It is believed to have taken part in the raids on London and Paris, but, owing to the great height and the small difference in size and appearance from the Gotha, identification is very difficult and unreliable.

The span of the upper planes is 12 feet less than the Gotha, and the sweep back is the same, about 3°. The central portion has neither sweep back nor dihedral angle, and the top and bottom planes are slightly unequal, owing to the arrangement of the Vee engine struts and nacelles, and are set at a small dihedral angle of 2° with a slight stagger. The tips are raked with rounded angles and the tips of the ailerons project forward beyond the tip of plane, similar to the Gotha, and both types are pushers, which necessitates cutting away the central portion of the trailing edge and reducing the chord to allow for clearance of the propellers.

Each motor is mounted on Vee steel tube struts running from the lower to the upper plane, and enclosed by the nacelles, and braced to the fuselage by steel tubing. There are two pairs of interplane struts on each side fixed at a slight outward angle, and the leading edge of top plane projects slightly in front of lower plane, and is braced by diagonal wires fixed to the lower ends of the outer pair of interplane struts.

There is a marked difference in the position of the ribs. Unlike the Gotha, they are fixed parallel to the axis of the fuselage, while in the Gotha they are at right angles to sweep back and leading edge, and are therefore at an angle with line of flight and axis of fuselage.

The tail plane is different from the Gotha, having a greater length and with the rudder is a return to the Albatross type. The rudder of the Gotha is more square, the front and rear edge being parallel, while the rudder of the F. F. Gotha II. is triangular. The fin is triangular and slightly rounded off on to the fuselage in front, similar to the English types of machines. The elevators and rudders are balanced and constructed of steel tubing very similar in manner to the Gotha.

The fuselage is rectangular in section, and the upper surface is parallel with line of flight, or horizontal when the machine is balanced or in equilibrium. The gunner's cockpit is placed in front with revolving gun ring, and immediately behind is placed the pilot's cockpit; behind this is the petrol tank between the two bomb racks, one on each side, with release gear. In the rear is the second gunner's cockpit, with gun ring, connected with trap-door behind, in bottom fuselage, though which the gunner is enabled to fire downwards or backwards at enemy machines.

Contrary to the usual German practise, the landing carriages are formed of two vertical struts with a diagonal rear strut fixed to base of fuselage, on which are mounted the axle and pair of wheels of rather a narrow track. The rubber shock-absorbers are of the usual German type. There is also a large stream-lined horizontal skid, the front and rear ends of which are fixed to two vertical steel tube struts, which are fixed to the base of Vee struts, which support the engine.

The tail skid is constructed of ash tipped with a steel shoe, and is fixed to a vertical steel tube running up and built into the fuselage.

The motors are mounted between two pairs of Vee struts connecting upper and lower planes, and each of the Benz engines is enclosed in a boat-shaped nacelle stream-lined to a pointed cap and boss behind, to which is fixed the propeller.

The radiator is of the honeycomb type, and is placed in front of the engines, which are a pair of Benz 225-h.p. six cylinders, developing the maximum power at 1,400 r.p.m.

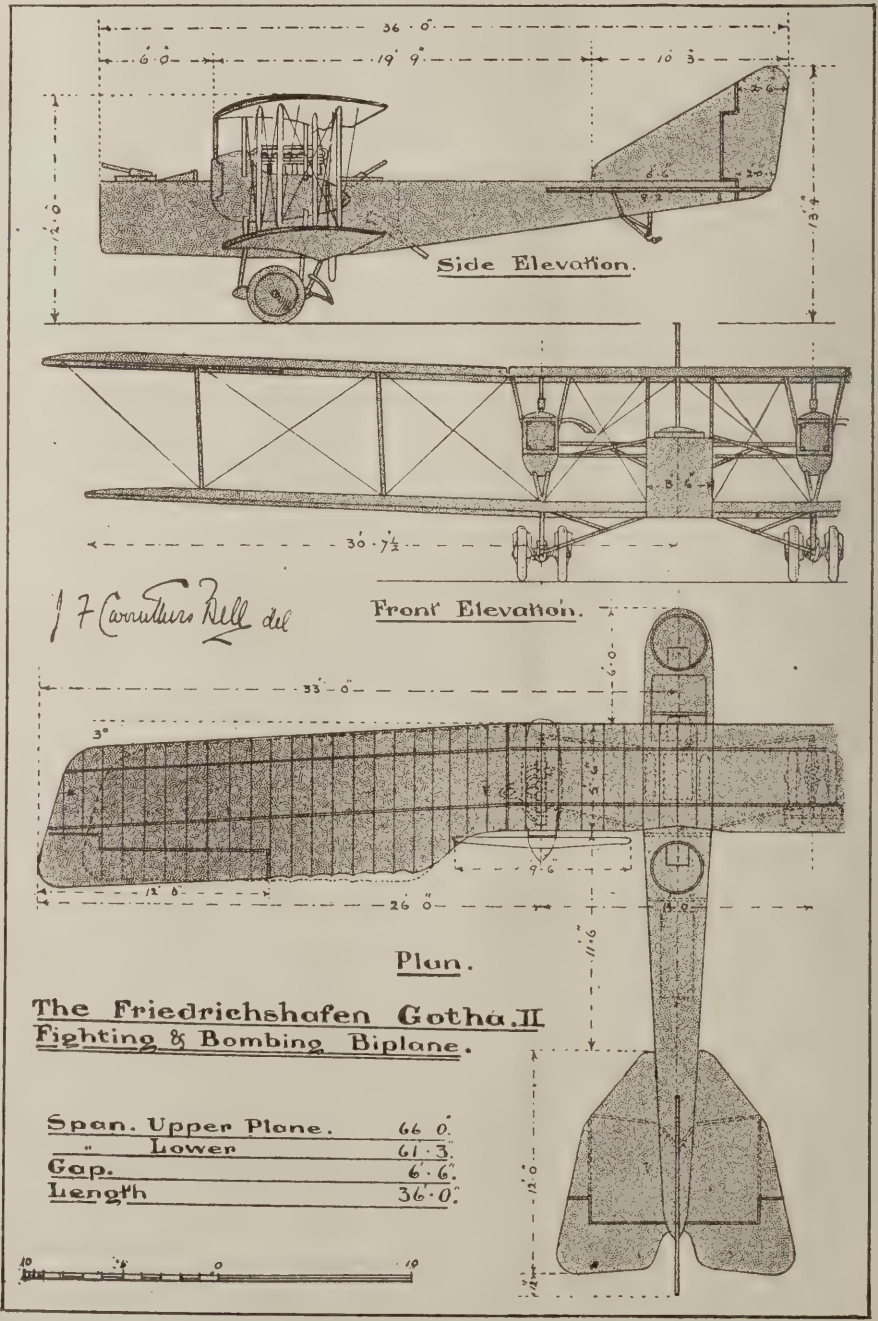
The petrol tank, together with the two gravity tanks, have seperate feeds, and have a capacity of 124 gals.

The bomb chambers are similar to the Gotha, and each chamber carries six bombs, and four incendiary bombs are carried under the fuselage horizontally one over the other, supported by steel clips.

The machine carries fuel for four hours' flight. The following are the approximate weights:—

	lbs.	lbs.
Weight of machine..................		4,300
Useful load, pilot and two........ gunners..............................	500	
Fuel	1,000	
Oil	200	
Guns, bombs, etc..................	800	
	——	2,500
Total load..............		6,800

The total wing area is 700 sq. ft.; this gives a load of 9¾ lb. sq. ft. of wing area, and a fraction over 15 lb. per horse-power. The wing loading appears to be excessive, but is in a measure counterbalanced by the moderate load per horse-power.



The Friedrichshafen Gotha II Fighting & Bombing Biplane.

Span. Upper Plane.	66 0.
" Lower	61 · 3.
Gap.	6' · 6".
Length	36' · 0".

CALCULATION OF STRESSES IN AEROPLANES

By S. E. SLOCUM, Ph.D.
Professor of Applied Mechanics, University of Cincinnati, Member S. A. E.

THE brief history of aviation up to the present time has been mainly a record of experimental achievement, as it is always necessary to determine the physical constants involved in a scientific problem of this nature before mathematical analysis can be applied to it. Such experimental research is now well systematized, and there are at present a considerable number of laboratories both in this country and abroad devoting their entire time to scientific research in aerodynamics. There has also been considerable advance made in the mathematical theory of aviation, such for instance as the work of Bairstow and Wilson, but much of this work is not yet generally accessible, while a large part of it is too highly technical to be within the grasp of those who are otherwise qualified for practical accomplishment in aeronautical work.

Under the pressure of military necessity the efforts of manufacturers and others interested in aviation have been concentrated on production, and there has been practically no attempt to educate the average engineer or layman interested in this line of work in the principles of aeroplane construction. Before aviation can become a standardized branch of engineering, however, it is necessary that a knowledge of the principles of construction and operation of aircraft be generally diffused. At present production of aircraft is, of course, paramount, but the future development of aviation depends largely on giving those not now specifically engaged in this line of work an intelligent understanding of the mechanics of aviation.

The object of the present paper is to add a small contribution to what has already been done in this line of explaining as simply as possible the four main items involved in the design of aeroplanes, namely,

1. The distribution of load;
2. The analysis of stresses in the spars;
3. The analysis of stresses in the lift and drift trusses;
4. The analysis of stresses in the fuselage trusses.

Principal Dimensions

The type of machine considered, as shown in Figure 1, is an American biplane, which is sufficiently standard to be suitable for purposes of analysis, although this particular model is not fast enough to meet war requirements.

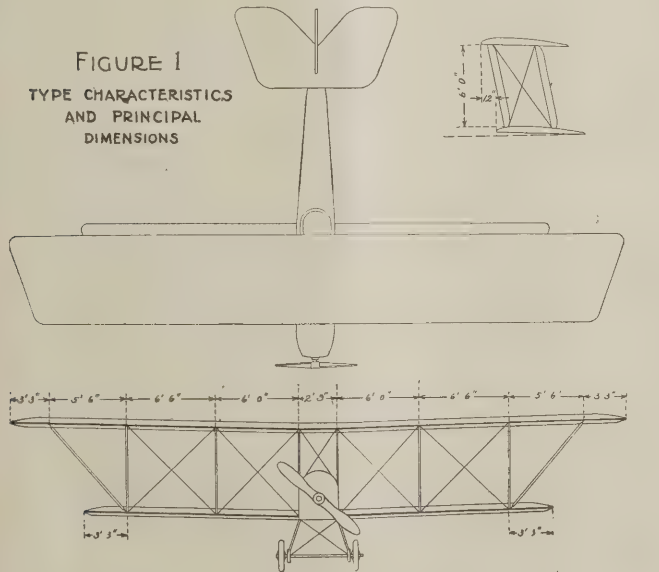

FIGURE 1
TYPE CHARACTERISTICS AND PRINCIPAL DIMENSIONS

The principal data needed for calculation are as follows:—

Total loaded weight, 2,000 lbs.
Total wing area, including ailerons, 472 sq. ft.
Weight of wings alone, 0.75 lbs. /ft².
Total weight of wings, 472 x .75 = 354 lbs.
Span of wings, 45' 3".
Chord of wings, 6' 6".
Gap between wings, 6' 6".

Type Characteristics

The principal structural features of the types of aeroplanes under consideration have all been determined from the results of experiments.

The chief characteristic is the aspect ratio, which is defined as

$$\text{Aspect ratio} = \frac{\text{Span of wing}}{\text{Chord of wing}} = \frac{45'\ 3''}{6'\ 6''} = 7.$$

The interplane truss (or "lift truss" as it is called), shown in front elevation in Figure 1, is the Pratt truss, long used by bridge engineers, and introduced into aeroplane construction by the well known American bridge engineer, Octave Chanute. The overhanging type of construction, formed by shortening the lower planes, was introduced by Henry Farman, one of the pioneers in aviation in France.

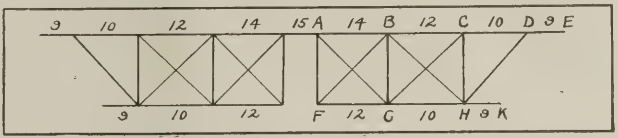

Figure 2. Relative proportions of panel loads

This braced girder type of construction seems to have the advantage in point of lightness and simplicity over any other form of construction of equal strength. The diagonals are wire, one set being stressed when the plane is in normal flight, and the other system being in action when the plane is resting on the ground, or flying in an inverted position.

The unequal panel length is a French invention, the effect of shortening the panels adjoining the fuselage being to reduce the stresses near the center; that is, to distribute the stresses more uniformly throughout the truss. In the present case the stresses could be reduced somewhat by making the panel AB say 6" shorter and adding this 6" to the next panel BC.

The reason for giving the upper plane a greater spread than the lower is because it has been found by experiment that the upper plane is more efficient that is it exerts a greater average lift, than the lower. This decrease in effective lift of the lower plane is due partly to the interference with the air currents produced by the fuselage, which is placed in the middle where the lift would otherwise be a maximum, and partly to the influence of the upper plane, which deflects the air currents downward on top of the lower plane, thereby partially reducing the suction, or negative pressure, on this surface. In general, it has been found that the upper wing of a biplane carries from 0.6 to 0.8 of the total load. The most efficient spacing for a biplane has been found by experiment to be when the gap between the wings is approximately equal to the chord of the wings.

The object in staggering the planes, that is, in placing the upper plane in advance of the lower, is to improve the lift of the upper plane, as experiments seemed to show that this construction increased the efficiency of the upper plane as much as 5 per cent. This conclusion, however, does not seem to be verified by recent experiments.*

The use of a trapezoidal form of wing with the short edge leading has been found to decrease the head resistance, or drift, somewhat, as compared with that for a wing of rectangular plan.

Distribution of Load

It has been found by experiment that besides the positive pressure on the under surface of an aerofoil, or wing, there is also a negative pressure, or suction, on the upper surface of the wings. The latter in fact is more important than the pressure on the surface directly exposed to the wind, making it necessary to attach the covering solidly to the back of the wing. For present purposes, however, we are only concerned with the total lift exerted on a unit area at any point, which is the numerical sum of the positive and negative pressures at this point.

It has also been found by experiment that the lift, or wing loading, for an aerofoil of constant cross-section varies along the span, being greatest at the center and falling off towards either end. The ratio of the loading per unit area at the center of the span to that near the wing tips has been found to depend on the aspect ratio of the aerofoil and also on its plan form, being smaller for the larger aspect ratio, and also smaller for wings with rounded tips.

---

* See monograph by L. Marchis included in the Second Annual Report of the National Advisory Committee for Aeronautics, 1916.

In the present case the total load supported is 2,000 pounds, of which the weight of the wings alone is 354 pounds. Since the wings are self supporting so far as the truss system is concerned, the stresses in the wing spars and lift trusses are calculated from the net load supported, namely 2,000 — 354 = 1,646 pounds. Since the total area of the planes is 472 sq. ft., the average load per sq. ft. of supporting surface is

$$\text{Average net lift} = \frac{1646}{472} = 3.487 \text{ lbs. per sq. ft.}$$

Considering the total weight lifted, the average is $\frac{2000}{472} = 4.24$ lbs. per sq. ft. This may be compared with the average lift for biplanes in general, which usually lies between 3 and 6.5 lbs. per sq. ft.

To determine the actual unit load for each panel, it is necessary to take into account the variation of lift along the span, as mentioned above. For the type under consideration this variation in pressure along the span may be represented by the numbers indicated in Figure 2, these numbers representing the relative proportions of the loading in the various panels. For example, the upper wing panel on either side of the center is assumed to carry $\frac{14}{15}$ as much load per sq. ft. as the center panel; while the panels at the tips of the wings carry $\frac{9}{15}$ as much per sq. ft. as the center panel, etc.

To find the unit load in each panel, let x denote the unit load for the center panel of the upper wing. Since the area of this panel is 2.75 × 6.5 = 17.875 sq. ft., the total load supported by it is 17.875x. Since the unit load on each of the adjoining panels is $\frac{14}{15}x$, and the area of these panels is 39 sq. ft. each, the total load supported by them is $2 \times \frac{14}{15}x \times 39$, etc.

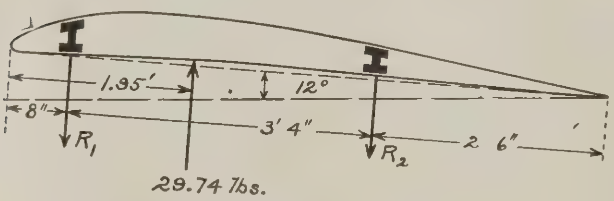

Figure 3. Resultant pressure and spar reactions

Therefore equating the total load supported by both wings to the net load carried, we obtain the equation

$$x\,[17.875 \times 2 \times \frac{14}{15} \times 39 + 2 \times \frac{12}{15} \times 42.25 + 2 \times \frac{10}{15} \times 35.75 + 2 \times \frac{9}{15} \times 14.625 + 2 \times \frac{9}{15} \times 14.625 + 2 \times \frac{10}{15} \times 42.25 + 2 \times \frac{12}{15} \times 39] = 1646$$

whence

$$x = 4.575 \text{ lbs. per sq. ft.}$$

$$\frac{14}{15}x = 4.270 \text{ lbs. per sq. ft.}$$

$$\frac{12}{15}x = 3.660 \text{ lbs. per sq. ft.}$$

$$\frac{10}{15}x = 3.050 \text{ lbs. per sq. ft.}$$

$$\frac{9}{15}x = 2.745 \text{ lbs. per sq. ft.}$$

which gives the unit loading in the various panels. According to this distribution, therefore, the upper plane carries 1022.5 lbs., or about 62 per cent of the net load. Including the weights of the planes themselves, the upper plane carries 1233 lbs., or 61 2/3 per cent of the total load.

Panel Loads on Front Spar

It is perhaps unnecessary to explain that the wings are built on two longitudinal members called spars, which carry a system of transverse ribs over which the fabric is stretched, and that the lift trusses connect the spars of the upper and lower wings. As the load is carried by the ribs to the spars and thence into the truss system, it is necessary to determine the load per running foot of spar. This, however, varies with the angle of inclination of the plane. That is to say, the center of pressure on the wing depends on its angle of incidence, by which is meant the angle which the chord of the wing makes with the direction of motion. As the angle of incidence increases, the center of pressure moves towards the leading edge of the plane, thereby increasing the load on the front spar and diminishing the load on the rear spar. Experiments do not fully agree on the location of the center of pressure for all angles of incidence, but within the narrow limits met in normal flight, the following tabular values, given by the English authority A. W. Judge, are sufficiently exact for all practical purposes.

Angle of Incidence.	Distance of Center of Pressure from Leading Edge.
0°	0.5 of Chord
2°	0.4 of Chord
6°	0.33 of Chord
12°	0.30 of Chord

To obtain the maximum load on the front spar, an angle of incidence of 12 v/o will be assumed. The center of pressure will then be at .3 × 6.5 ft. = 1.95 ft. from the leading edge.

Now consider the center panel of the upper wing, and take a transverse strip of this panel one foot in width. The area of this strip will then be 6.5 sq. ft., and the total load on it will be 6.5 × 4.575 = 29.74 lbs., which may be considered as concentrated at a point 1.95 ft. from the leading edge, as just explained. Representing the reactions of the front and rear spars by R_1 and R_2 respectively, as shown in Figure 3, we find by taking moments that $R_1 = 18.3$ lbs. Since we are considering a strip one foot wide, this reaction represents the load per running foot on the front spar. Using the proportions indicated on Figure 2, we then have the following values:—

Loads on Front Spar.

Center panel	18.3 lbs. per linear foot.
4th panel from either end	$\frac{14}{15} \times 18.3 = 17.08$ lbs. per linear foot
3rd panel from either end	$\frac{12}{15} \times 18.3 = 14.64$ lbs. per linear foot.
2nd panel from either end	$\frac{10}{15} \times 18.3 = 12.20$ lbs. per linear foot.
End panels	$\frac{9}{15} \times 18.3 = 10.98$ lbs. per linear foot.

Bending Moments in Spars

Both upper and lower spars are hinged at their point of attachment to the center panel, or fuselage, namely at the points lettered A and F in Figure 1. The upper spars therefore must be treated as a continuous beam of four spans, and the lower spars as a continuous beam of three spans. Since the spars are hinged at A and F, the moments at these points are zero. Also since the wing tips DE and HK act like simple cantilevers, the moments at D and H are

$$M_d = M_h = 10.98 \times 3.25 \times 1.625 = 58 \text{ ft. lbs.}$$

To determine the moments at the intermediate points B, C and G it is necessary to apply the theorem of three moments for continuous beams.* This may be stated as follows:—

Let M_1, M_2 M_3 denote the moments at three consecutive supports of a continuous beam, l_1, l_2 denote the lengths of the two spans considered, and w_1, w_2 the uniform load per foot on these spans. Then the following relation always exists:—

$$M_1 l_1 + 2M_2 (l_1 + l_2) + M_3 l_2 = \frac{w_1 l_1^3 + w_2 l_2^3}{4}.$$

In the present case, consider first the upper front spar, and write the theorem of three moments first for the three supports A, B, C, and then for the three supports B, C, D. We thus obtain the following equations

$$6M_a + 2M_b (6 + 6.5) + 6.5\ M_c = \frac{17.08\ (6)^3 + 14.64\ (6.5)^3}{4}$$

$$6.5M_b + 2M_c (6.5 + 5.5) + 5.5M_d = \frac{14.64\ (6.5)^3 + 12.20\ (5.5)^3}{4}$$

Since $M_a = 0$ and $M_d = 58$ ft. lbs., these two equations involve only the two unknowns M_b and M_c. Solving simultaneously for these two unknowns we find

$$M_b = 69 \text{ ft. lbs.},\ M_c = 31 \text{ ft. lbs.}$$

For the lower front spar it is only necessary to apply the theorem of three moments once, giving the equation

$$6M_f + 2M_g (6 + 6.5) + 6.5M_h = \frac{14.64\ (6)^3 + 12.2\ (6.5)^3}{4}$$

Since $M_f = 0$ and $M_h = 58$ ft. lbs., the only unknown in this relation is M_g, which is found to be

$$M_g = 50 \text{ ft. lbs.}$$

Reactions at Panel Points

Having determined the bending moments in the upper and lower front spars, the reactions at the panel points may next be found. Consider first the upper spar, and begin at the right end. Taking a section through C, the moments and forces acting on the part C E cut off are as shown in Figure 4. Denoting the rection at D by R_d and taking moments about C we obtain the equation

$$10.98 \times 3.25 \times 7.125 + 12.2 \times 5.5 \times 2.75 - R_d\ 5.5 = 31,$$

whence

$$R_d = 74.2 \text{ lbs.}$$

Next take a section through B and write the moment equation for the part on the right of the section, as indicated in Figure 5, giving the equation

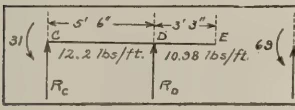

Figure 4

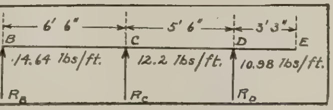

Figure 5

$$10.98 \times 3.25 \times 13.625 + 12.2 \times 5.5 \times 9.25 + 14.64 \times 6.5 \times 3.25 - 74 \times 12 - R_c \times 6.5 = 69,$$

whence

$$R_c = 70.4 \text{ lbs.}$$

Proceeding similarly for the other reactions, we find

$$R_b = 116.2 \text{ lbs., and } R_a = 47.0 \text{ lbs.}$$

For the lower front spar the results are

$$R_h = 76.6 \text{ lbs.},\ R_g = 90.7 \text{ lbs.},\ R_f = 35.6 \text{ lbs.}$$

Stresses in Lift Truss

From the reactions just found the stresses in the lift truss connecting the upper and lower front spars may be found. In normal flight only the diagonals FB and GC are stressed. Beginning at D, the forces meeting at this point are as shown in Figure 6. From the conditions of equilibrium, namely

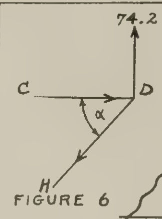

FIGURE 6

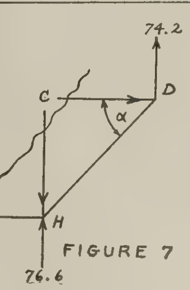

FIGURE 7

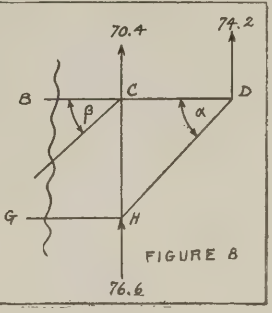

FIGURE 8

$$\text{Sum of horizontal force components} = 0$$

and

$$\text{Sum of vertical force components} = 0$$

which are usually written simply as $\Sigma H = 0$ and $\Sigma V = 0$, we have

$$DH \sin \alpha = 74.2$$

whence $DH = 101$ lbs.

Also $CD = 74.2 \tan \alpha$

whence $CD = 68$ lbs.

Now take a section diagonally through the panel CRHG, as shown in Figure 7, and apply the condition that the stresses in the members cut must equilibrate the external forces on one side of the section. In the present case applying the condition $\Sigma V = 0$, we have

$$CH = 76.6 + 74.2 = 151 \text{ lbs.},$$

and similarly from $\Sigma H = 0$ we have

$$GH = CD = 68 \text{ lbs.}$$

Now proceed by taking a section vertically through the panel BCHG, as shown in Figure 8, and again apply the principle that the internal and external forces must equilibrate. Then from $\Sigma V = 0$ we have

$$GC \sin \beta = 70.4 + 74.2 + 76.6$$

whence $GC = 326$ lbs.

while from $\Sigma H = 0$ we have

$$BC = GH + GC \cos \beta$$

whence $BC = 308$ lbs.

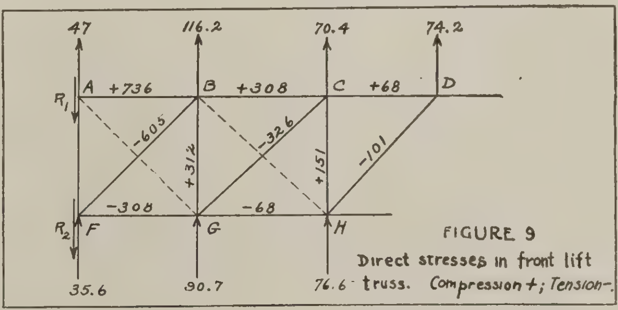

FIGURE 9
Direct stresses in front lift truss. Compression +; Tension -.

Proceeding in this manner we finally obtain all the stresses in the lift truss, the results being as indicated on Figure 9.

(*To be continued.*)

---

* An elementary proof of this theorem, without calculus, was published by the writer in *Engineering News*, Feb. 19, 1914, and is also given in Chapter 6 of his book on "Resistance of Materials," published by Ginn & Co.

NAVAL and MILITARY AERONAUTICS

Key to Abbreviations

AAD—Assigned to active duty.
ADO—Report to Aviation Supply Depot, Dayton, Ohio.
ADT—Report to Aviation Supply Depot, Dallas, Texas.
AEF—On duty with the American Expeditionary Forces.
AFO—Report to Aviation Supply Depot, Fairfield, O.
AGC—Report to Aviation Supply Depot, Garden City, L. I., N. Y.
AHT—Report to Aerial Gunnery School, Houston, Texas.
AMV—Report to Aviation General Supply Depot, Morrison, Va.
AOV—Report to School for Aerial Observers, Hampton, Va.
APR—Report to School of Aerial Photography, Rochester, N. Y.
ASM—Report to Aviation Mechanics' Training School, St. Paul, Minn.
BST—Report to Brooks Field, San Antonio, Tex.
CAF—Report to Carlstrom Field, Arcadia, Fla.
CAG—Report to Camp Hancock, Augusta, Ga.
CAP—Commissioned as Captain, Aviation Section, Signal Corps.
CCI—Report to Chanute Field, Champaign, Ill.
CDT—Report to Aviation Concentration Camp, Dallas, Texas.
CGC—Report to Aviation Concentration Camp, Garden City, L. I., N. Y.
CGS—Report to Aviation Concentration Camp, Greenville, S. C.
CWJ—Report to Camp John Wise, San Antonio, Texas.
CLR—Commissioned as Colonel, Aviation Section, Signal Reserve Corps.
CMV—Report to Aviation Concentration Camp, Morrison, Va.
COL—Commissioned as Colonel, Aviation Section, Signal Corps.
CPR—Commissioned as Captain, Aviation Section, Signal Reserve Corps.
CRI—Report to Chanute Field, Rantoul, Ill.
CSO—Report to the Chief Signal Officer, Washington, D. C.
CUI—Report to School of Military Aeronautics, Cornell University, Ithaca, N. Y.
CWT—Report to Call Field, Wichita Falls, Texas
DAF—Report to Dorr Field, Arcadia, Fla.
DIK—Report to Camp Dick, Dallas, Tex.
DIS—Honorably discharged from service.
EEP—Report to Essington Field, Essington, Pa.
ELA—Report to Eberts Field, Loanoke, Ark.
EOT—Report to Ellington Field, Olcott, Texas.
FLR—Commissioned as First Lieutenant, Aviation Section, Signal Reserve Corps.
FLT—Commissioned as First Lieutenant, Aviation Section, Signal Corps.
FOB—Report to Fort Omaha Balloon School, Omaha, Neb.
FRF—On duty requiring regular and frequent aerial flights.
FSO—Report to Fort Sill School for Aerial Observers, Fort Sill, Okla.
GIT—Report to School of Military Aeronautics, Georgia Institute of Technology, Augusta, Ga.
GLC—Report to Gerstner Field, Lake Charles, La.
HHN—Report to Hazelhurst Field, Mineola, L. I., N. Y.
JHU—Report to School of Military Aeronautics, John Hopkins University, Baltimore, Md.
JMA—Rated as Junior Military Aviator.
JRC—Report to Jackson Field, Riverside, Cal.
KST—Report to Kelly Field, So. San Antonio, Tex. (When specified in the order, the number of the field is given in parentheses)
LDT—Report to Love Field, Dallas, Tex.
LHV—Report to Langley Field, Hampton, Va.
LTC—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Corps.
LTR—Commissioned as Lieutenant-Colonel, Aviation Section, Signal Reserve Corps.
MAC—Report to March Field, Allesandro, Cal.
MAJ—Commissioned as Major, Aviation Section, Signal Corps.
MAT—Report to Mather Field, Sacramento, Cal.
MDO—Report to McCook Field, Dayton, Ohio.
MIT—Report to School of Military Aeronautics, Massachusetts Institute of Technology, Boston, Mass.
MJR—Commissioned as Major, Aviation Section, Signal Reserve Corps.
MMP—Report to Middletown Aviation Supply Warehouse, Middletown, Pa.
MSC—Report to Radio School, Maryland State Agricultural College, College Park, Md.
OSU—Report to School of Military Aeronautics, Ohio State University, Columbus, Ohio.
PFO—Report to Post Field, Fort Sill, Okla.
PMT—Report to Park Field, Millington, Tenn.
PRC—Appointment to Aviation Section declined; prefers retaining previous commission.
PUP—Report to School of Military Aeronautics, Princeton University, Princeton, N. J.
PWM—Report to Payne Field, West Point, Minn.
REL—Relieved from present duty.
REV—Recently issued order is revoked.
RII—Report to Repair Depot, Indianapolis, Ind.
RRV—Report to Aviation Depot, Richmond, Va.
RSD—Report to Rockwell Field, San Diego, Cal.
RTR—Retransferred to organization attached to previous assignment to aviation duty.
RWT—Report to Rich Field, Waco, Tex.
SBI—Report to Scott Field, Belleville, Ill.
SAG—Report to Souther Field, Americus, Ga.
SGS—Report to Camp Sevier, Greenville, S. C.
SLR—Commissioned as Second Lieutenant, Aviation Section, Signal Reserve Corps.
SLT—Commissioned as Second Lieutenant, Aviation Section, Signal Corps.
SMM—Report to Selfridge Field, Mount Clemens, Mich.
SPD—Report to Col. B. P. Disque, Spruce Division, Yeon Bldg., Portland, Ore.
TFT—Report to Taliaferro Field, Fort Worth, Texas. (When specified in the order, the number of the field is given in parentheses)
TMA—Report to Taylor Field, Montgomery, Ala.
UCB—Report to School of Military Aeronautics, University of California, Berkeley, Cal.
UIU—Report to School of Military Aeronautics, University of Illinois, Urbana, Ill.
UTA—Report to School of Military Aeronautics, University of Texas, Austin, Tex.
VBW—Report to Vancouver Barracks, Washington.
WAC—Report to Aviation Concentration Camp, Waco, Tex.
WCS—Wire to the Chief Signal Officer upon arrival.
WCW—Report to War College Division, General Staff, Washington, D. C.
WFO—Report to Wilbur Wright Field, Fairfield, Ohio.

Note 1.—Report to points named in order given.

Note 2.—Report to Construction Company, Fort Wayne, Mich.

Note 3.—Report to General Supply Depot, Omaha, Neb.

Note 4.—Report to Capt. Paul B. Holmes, 870 Woodward Ave., Detroit, Mich.

Note 5.—Report to Signal Corps Recruit Bureau, Fort Wayne, Mich.

Note 6.—Report to General Supply Depot, Atlanta, Ga.

Note 7.—Report to District Manager of Equipment, Chicago, Ill.

Four Nieuports and a Spad being groomed for work in Flanders

FOREIGN NEWS

BELGIUM

The Belgian official statement for May 9th reports the following aerial activity:

"Enemy aviators bombed several of our cantonments without success. Our aviators were very active."

FRANCE

The French official announcement for May 7th says:

"On May 6th four German aeroplanes were brought down in the course of an aerial fight. Ten others were sent down damaged within their own lines. During the same day our bombarding machines dropped 4,000 kilograms of projectiles on the stations of Fluille, Martel, Merresis, Ham, Guiscard, Noyon, and Vermond."

The text of the French War Office communiqué for May 8th reports the following aerial operations:

"Yesterday we brought down in air fighting four German machines. Ten others fell out of control within the German lines.

"We dropped four and one-half tons of bombs on the Flaville, Martil, Messines, Ham, Guiscard and Noyon stations."

The French War Office announced on May 10th that Sub-Lieutenant Rene Fonck brought down six German aeroplanes on May 9th—a performance that has never been equaled. Before leaving the aerodrome for his first flight, Fonck declared that he would avenge the death of his friend, Lieutenant Chaput, who was downed on May 7th, credited with twenty victories. The official statement follows:

"Yesterday Lieutenant Fonck brought down six German biplanes in the course of two patrols. He downed the first two in ten seconds, the third five minutes later, and the other three in the course of the second patrol."

The French official announcement issued on May 12th, reports the following aerial activity:

"On May 10, despite the bad weather, our pursuit aeroplanes displayed activity. Two German machines were brought down and eight were seriously damaged. On May 11 a German captive balloon was set afire by our pilots.

"On May 10 and 11 our bombing machines dropped 7,000 kilos of projectiles on railway stations, depots and cantonments of the enemy, notably in the regions of Noyon, Chauny and Flavy-le-Lartel. At this last mentioned place several fires were observed."

Sub-Lieutenant Nungesser, the leading French aviator, brought down on May 7th his thirty-third and thirty-fourth German machines and damaged another, which will be undoubtedly placed to his credit. On May 5th he achieved two victories. Nungesser, during three years of air fighting, has been wounded seventeen times, and has served on fifty-two bombing expeditions.

Lieutenant Chaput, with sixteen Germans to his credit, Sub-Lieutenant Demeuldre, with thirteen victories, and Captain Mieffre, with a remarkable record, have been lost within the last few weeks in aerial combat.

A Paris newspaper states that the month of April confirmed the Allies' supremacy in the air. The French brought down 120 machines. Fourteen machines were brought down by Americans.

GERMANY

Reporting on the operations of "the last few days," the German official statement of May 9th says:

"The enemy has lost thirty-seven aeroplanes in the last few days in aerial fighting and by fire from our anti-aircraft guns."

"On Thursday afternoon and evening strong enemy air squadrons carried out bombing attacks against the Mole at Zeebrugge without causing damage of military importance," the German War Office announced on May 10th. "As a result of the bombs a Zeebrugge church was damaged and three Belgians were killed and four wounded. Three hostile aeroplanes were shot down."

The Berlin official war office announcement for May 12th reports that "In aerial fighting during the last two days, nineteen enemy aeroplanes were shot down, twelve of them being brought down by the fighting echelon formerly led by Baron von Richthofen."

GREAT BRITAIN

A British War Office announcement on May 4th, describing operations against the Turks on the Palestine front, reports the following aerial activity:

"Our air service attacked troops and rolling stock on the Hedjaz Railway, in the vicinity of Allan, and on the Wadi Sir, south of Es-Salt, with bombs and machine-gun fire. Two of our machines failed to return."

The British official statement on aerial operations issued by the War Office on May 6th states:

"There was a dense mist Saturday until evening, when reconnaissance was possible. Nine tons of bombs were dropped on the Caulnes railway junction and on Bapaume, Armentieres, Merville, and Estares.

"There was very little air fighting. One hostile machine was brought down by our aviators and four others were disabled. Two of our machines are missing. Two of our machines, missing since May 3, have since returned.

"After dark, although conditions were still unfavorable, more than three tons of bombs were dropped on the Chaulnes railway junction and on Bapaume. All our machines returned."

Successful aerial combats are described in the official statement of May 8th as follows:

"Flying again was impossible Tuesday (May 7th) until after 5 o'clock, because of a pouring rain. The weather then cleared suddenly, and machines were sent out. Four hundred bombs were dropped on different targets all along the front. Twelve hostile machines were brought down in air fighting, eight of which were accounted for in a big encounter in the neighborhood of Doual. A German observation balloon was brought down in flames. None of our machines are missing."

The British official statement for May 9th reports intense and extensive bombing activity on the part of the air service. The text of the statement follows:

"Ten tons of bombs were dropped on Le Cateau, Cambrai, Bapaume and on the docks and mole at Zeebrugge.

"In the northern area there was strenuous fighting throughout the day. Twenty-two hostile machines were shot down, seven others were brought down out of control, and another German machine was shot down by our machine-gun fire. Seven of our own aeroplanes are missing.

"Owing to the mist only a few other aeroplanes were able to fly after dark. A ton of bombs was dropped on the railway stations of Douai and Marcoing. All machines returned."

The official announcement on aerial operations issued on May 10th reports numerous aerial victories on the part of British aviators and successful bombing raids as follows:

"The cloudless weather on Thursday enabled our aeroplanes to carry out a full day's work. More than twenty-four tons of bombs were dropped on different targets, including important railway stations at Tournay, Marcoing, Chaulnes, and Cambrai, and billets at Carvin, Péronne, and Chipilly, and the docks at Zeebrugge.

"Fighting in the air was more or less continuous, and it was particularly fierce toward dusk. Twenty-seven German machines were downed, twelve were driven down out of control, and four hostile observation balloons were destroyed. Six of our machines are missing.

"During the night four and one-half tons of bombs were dropped on the docks and at the entrance of the canal at Ostend and three and one-half tons on Péronne, Chaulnes, and Bapaume. All of the machines returned."

Fine weather stimulated aerial activity, according to the announcement of May 11th, which reads:

"Low clouds and mist prevented flying on Friday until 5 P. M. After this hour the weather cleared on a small part of the front and great aerial activity took place in this sector until dark.

"Over fourteen tons of bombs were dropped on Péronne, Bapaume, Thielt, Douai, Zeebrugge, and the docks of Bruges.

"Hostile scouts were very active and made repeated attacks on our bombing machines. Eight German aeroplanes were brought down in air fighting and six were driven down out of control. Nine of our machines are missing. One reported missing on Tuesday has returned."

The British official announcement issued on May 12th reports the following aerial activity:

"On Saturday, except for a short period of clearness in one sector, enabling reconnoissance and bombing, the whole front was enveloped in mist throughout the day. One hostile machine was brought down in the air fighting. Two of ours are missing. Three other German machines were brought down Friday, in addition to the eight previously reported."

In a recent issue of London "Flight" we learn that it is reported that between March 21st and April 3rd, British airmen fired 1,139,525 rounds of small arm ammunition from their machine-guns into German troops and transport columns. That estimate, however, is very well inside the mark, since official figures record that in two days over 700,000 rounds were expended by low-flying machines. Regarding bombing, the R. A. F., during the latter phases of the present battle, dropped 303¼ tons of bombs on German billets, railheads, dumps, gun positions and concentrations of troops. Day bombing accounted for 179¼ tons of bombs, while 151 tons were dropped by night bombing squadrons. The greatest weight of bombs dropped in any one day was 28¾ tons, while the greatest in any one night totaled 31 tons.

ITALY

"In an air fight Saturday (May 4th), in the Gulf of Trieste, three Austrian seaplanes were brought down," said the official statement of May 7th from Rome. "All of our machines returned safely."

Italian aviators, according to reports, have destroyed the hydro-electric plant in the Trentino, which supplies the power for the Austrian railways leading to the front.

An official statement from London on May 9th reports very successful aerial operations on the part of the British airmen on the Italian front, as follows:

"Two successful raids were carried out and we captured a few prisoners. The artillery is more active. Hostile batteries were engaged with satisfactory results. Our air forces, since the last report, have destroyed seventeen enemy aeroplanes. None of ours was lost."

A report from Rome on May 9th says that British aviators bombed the aviation ground at Motta di Livenza.

Intense aerial activity all along the Italian front resulted in the destruction of five enemy machines, the Italian War Office announced on May 10th.

"During the last few weeks the Italian hydroaeroplanes have been very active, accomplishing daring raids," says an official dispatch from Italy received on May 10th. "On Wednesday last (May 8th) three hydroaeroplanes flew over Trieste at a low altitude for observation purposes, while four Wisinest hydroplanes belonging to the enemy gave chase. After completing their mission our machines pretended to desire to escape, and drew the enemy planes toward the Italian coast, where five of our own chasers immediately engaged them.

After a short engagement, one of the enemy hydroaeroplanes was hit and fell into the sea. All of our machines returned safely to their base."

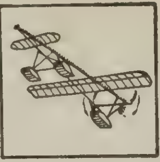
The Italian War Office announcement of May 11th says:

"There was intense aircraft activity. One of our airships dropped a ton of bombs on the Mattarello railway station. Three hostile aeroplanes were brought down and one Drachen was set afire by British airmen."

On May 12th, the War Office announced that seven hostile aeroplanes were brought down.

MODEL NEWS

Edited by John F. McMahon



Model Aeroplane Building as a Step to Aeronautical Engineering

By John F. McMahon

WERE you to throw a pie plate from you with sufficient force, it would make a graceful glide, and the glide would be in proportion to the energy expended in throwing this plate.

An aeroplane works on much the same principle, the force acting on the aeroplane to keep it moving is called the "Thrust," and is made by the engine turning the propeller, and screwing its way into the surrounding atmosphere. From this it can be seen that an aeroplane must move forward in order to remain aloft and the speed that it must move forward is gauged by the weight of the machine, size of wings, etc.

In figure 1 we see how the forces just mentioned act on an aeroplane wing, arrow *A* shows direction and angle of plane, *B* shows wind acting on the under surface of the wing, *C* shows how arrow *B* is cause of *C* or lift that machine gets from the forward motion. But as this is more technical than we care about going into at this stage of our course, we will leave it for the present and proceed with the simpler part of our work.

Another item we must remember is control. Without this the aeroplane would float around like a leaf in the wind. To control a machine it is necessary to have a tail for horizontal control, wing tips or "ailerons" for lateral balance, and a rudder for steering left or right. Another system for balancing a machine is to warp or to twist the wings. This last system is not as much in use as the former because the wing must be made flexible, and of course cannot be braced as well as the "aileron" system. In the models we are to build for the present it is not practicable to fit the wings with "ailerons," but it is well at all times to keep them in mind as a great many faults in a model can be corrected by knowing that a slight twist of the wing might correct the fault.

A model can be balanced for flight without the use of "ailerons" by locating the center of gravity properly causing the model to be almost inherently stable, to learn more about this part of our course we will build a small glider. This glider can be made inexpensively from wood by the following instructions and referring to the accompanying drawings.

The main plane is made of soft white wood 20 inches long and 3 inches wide and planed to the section shown at figure 4, after which it may be sandpapered and varnished to a smooth finish. The tail is next made in the same way, the size of this being 7 inches by 3 inches. The section is the same as the cross section of the wing as in figure 4. The body is also made of soft white wood to the form and size shown at figure 6. For efficiency it is better to round the corners, and if possible to the form of a bird's body as shown in cross section, figure 7.

The reason for leaving the top flat is because we will have to have a surface to attach the plane, and tail, too. For directional control we will use a piece of thin aluminum or tin, cut to shape and size in figure 5.

Our next step is to drill out a hole in the nose of the body ½" in diameter as shown in figure 8 and fill it with lead. This is done to bring the balancing point as far forward as possible. About an ounce of lead will be sufficient.

To assemble refer to figures 8 and 9, and proceed as follows:

Attach the rudder in place by cutting a slot in the tail of the body, insert tongue of rudder, wrap with thread and glue, next put tail in position with small nails and glue, next put main plane in place, fastening with rubber bands only. There are two reasons for using the rubber bands, first to allow free movement in plane for easy adjustment and secondly, should glider come down sharply on its nose, the wing would move forward freely, and not break off, which would happen if it was fastened rigidly.

To adjust the model for flight proceed as follows: Grasp the model lightly between the fingers and locate point where model balances evenly, mark this point with pencil on paint.

Next place leading or entering edge of plane even with this point, and insert a small block of wood between the plane and the body. This is done in order to give the plane an angle of incidence which is described in figure 1.

To fly, select some high ground, or the side of a hill, hold the body of the model firmly in the hand, face into the wind, and throw the glider from you on a line with the shoulders. Never launch a model upward, it would be better to aim it at an imaginary point on the ground about 100 feet away. The reason for this is, if not balanced properly it will make a sharp accent, lose momentum, and promptly slide tail first to the ground. Should it do this, slide the plane back toward the tail about ½ inch and repeat the performance. If it should dive sharply to the earth, slide the plane a little forward, and so on, until model makes perfect flights.

If constructed and balanced properly flights of from 30 seconds to 1 minute can be accomplished. We are now past the first step of aeronautics.

(To be continued)

Ralph E. Olson in Aviation Service

Ralph E. Olson, who will be remembered as an old model flyer, is with the Aviation Signal Corps at Kelly Field, Texas. He is doing some experimenting with models during his spare time, and we expect to publish some of his work in an early issue of this paper. He wishes to be remembered by his old model friends.

Aeronitis is a pleasant, a decidedly infectious ailment, which makes its victims "flighty," mentally and physically. At times it has a pathologic, at times merely a psychologic foundation. It already has affected thousands; it will get the rest of the world in time. Its symptoms vary in each case and each victim has a different story to tell. When you finish this column YOU may be infected, and may have a story all of your own. If so, your contribution will be welcomed by your fellow AERONUTS. Initials of contributor will be printed when requested.

How to Behave on the Flying Field

Never go on to the flying field with the *common mob. Wait* until the section has marched out and then *Drift Leisurely* out, an hour or so *late.* This will show Lt. Wells that flying means *nothing* in your young life and will *strongly* ingratiate *you* in *his* favor.

* * *

On the way *out* cross the landing field, forcing a couple of planes to turn out of your way, if *possible.* Your *courage* and *daring* will be greatly admired by *everyone.*

* * *

As *soon* as you reach the *Field lay* your helmet and extra garments on the *Gasoline car. Sit* down somewhere on the car if there are any vacant seats. The *driver* will be *greatly* pleased at this trifling courtesy. If all *seats* are taken, promenade up and down *in front of* the fence, *walking* over the *wind indicator* as many times as convenient. If no seats are vacated, *arrange* yourself on the *ground* and try to *sleep.* Everyone will then know that you are an *old* flier and that you do not *care* to watch the *landings* and the *take offs.*

* * *

Never appear *interested* in the aeroplanes or their actions. This is only done by *newcomers* who are *waiting* for their first *joy ride.*

* * *

After you have *been* on the field *ten* or *fifteen* minutes, quietly approach *Lt. Wells* and *ask* to be excused to go to the Y. M. C. A. to get a cup of *chocolate.* This permission will be *happily* granted.

* * *

When you get to the Y. M. C. A., do not return until the next *morning.*

* * *

If you do not get there the first time keep on *trying.* This will show the lieutenant that *you* do not go after a thing *half-heartedly.* From *then* on he will be *especially* interested in your case.

* * *

Always take a book along with *you* to read. Your literary *turn* of mind will thus be *indicated* and you will *probably* be rewarded with an extra *ride*—possibly by the Lieutenant *himself.*

* * *

If an accident occurs, *rush* out to the machine and *cluster* around. Do not *hesitate* to take pieces of the wreckage for mementos. Get the *Altimeter* or the *Carburetor* or something that can be easily *packed* for *transportation.*

* * *

When the class is dismissed *scramble* for the barracks. Do not *wait* for formations or *roll-call* or *anything* like that. Make it *snappy. Try* to be the *first* one to reach the barracks. Lt. Wells will be *agreeably* surprised at this show of *speed.*

* * *

—From "The Wing Slip," published weekly at one of the American Aviation Camps in France.

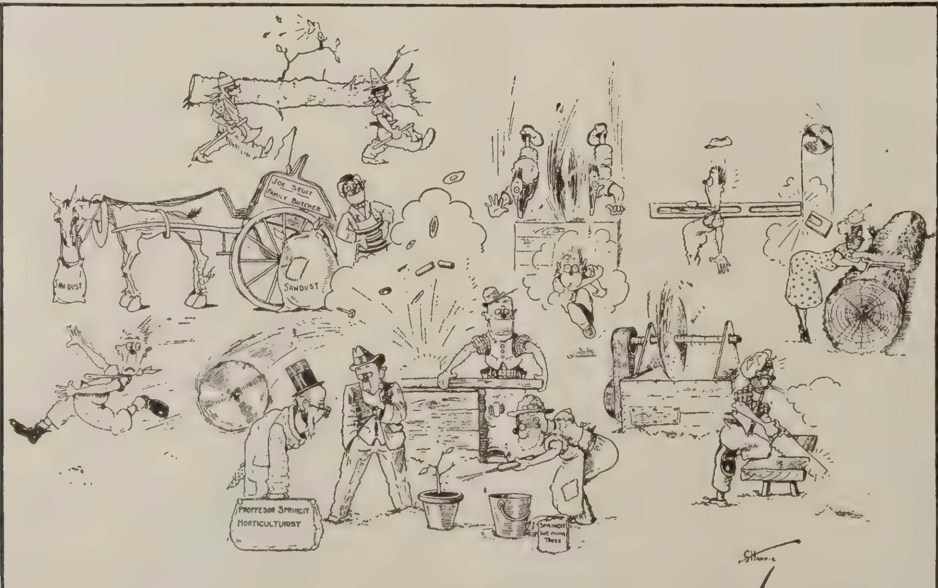
A Proper Answer

A young lady recently sent this extraordinary request to the editor:

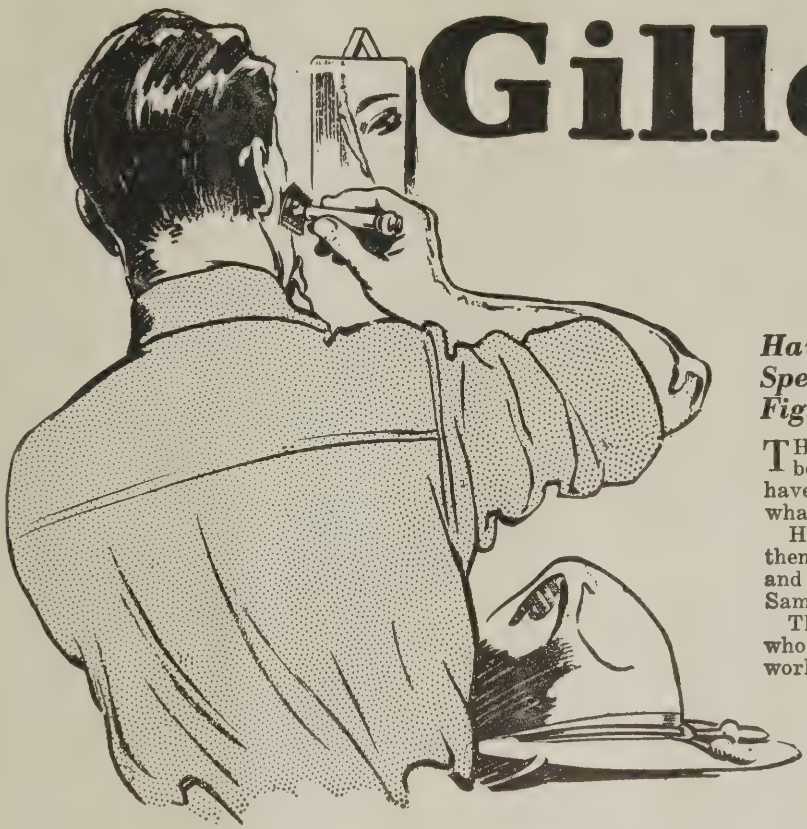
"Do you think it right for a girl to sit in a man's lap, even if she is engaged?"

The editor spent some time in thought, and then answered her as follows:

"Yes, if it were our girl and our lap. Yes, again, if it were some other fellow's girl and our lap. But if it were our girl and some other fellow's lap, emphatically no. We don't approve of such frivolity."



Scenes in an aircraft factory. The Saw Mill. This exclusive photo from "The Aeroplane" shows all of the processes in aeroplane woodworking construction, from the conference between the works manager on accelerating the growth of trees to the last finishing process



Gillette
Safety Razor

Have You Seen the New Gillettes Specially Designed for the Fighting Man?

THESE models were designed by members of the Gillette Organization who have seen service with the Colors and know what the soldier is up against.

Hundreds of officers and men are buying them—the U. S. Service Set in metal case, and the new Khaki-covered sets for Uncle Sam's soldiers and officers.

The Gillette is the one razor for the man who is doing things—the one razor with world-wide use and reputation.

When a man wants new Blades he can get them at any Post Exchange or Y. M. C. A. Hut—here in America or Overseas.

Our Paris Office carries stocks—is constantly supplying the American Expeditionary Forces. Gillette Safety Razors and Blades on sale everywhere in France, England, Italy and the Eastern battle fronts.

The Army of the United States Is Shaved Clean

No matter how a man shaved before he went into the Service, he is pretty sure to come out of the war a Gillette user.

The first thing he'll note among his camp mates is that more of them are shaving with the Gillette than with all other razors put together.

He'll see Gillette users in his squad lather up, shave clean, splash the soap off, tuck the razor away, and be standing at attention in the inspection line —all in five minutes.

When he gets Overseas, everything is the Gillette, from the left flank of the British line in Belgium clear around through France and Italy and on the battle fronts of the East.

Soon or late, every man who is doing things comes to the Gillette. They belong together. Ten million up and doing men all over the world had discovered the Gillette before the war broke out. The war simply made the Gillette prove itself under extreme conditions—as no other razor has or can.

It has thrown the spotlight on the Gillette Blades—on the Gillette principle of No Stropping—No Honing—on the Gillette idea of a simple, compact shaving outfit, no strops or hones to clutter up the kit—on the Gillette contention that a man's daily shave should be an incident and not a ceremony.

sion about the formation of a company to manufacture military aeroplanes for the Government. With Mr. Borglum at the time of the encounter on the train was Hugo C. Gibson, an engineer, associated with the British Munitions Ministry at its New York office, 120 Broadway.

In a statement by Mr. Mix, which forms the principal documentary exhibit, Mr. Mix says that "these two men intimated to me that they could produce designs for a plane that would be faster than the Albatross." The Dodge Company had the latest Albatross designs and was intending to build a machine of that type.

Mr. Mix became interested, he saw Mr. Gibson in New York, and says that Mr. Gibson told him that Mr. Borglum had confidential relations with the Government which would be to the advantage of the Dodge concern as well as to themselves. That was in December. On January 2 President Wilson gave to Mr. Borglum a letter authorizing him to make inquiries in official quarters to ascertain the truth of allegations Mr. Borglum had made in connection with the military aircraft production program. Soon afterward Mr. Mix met Mr. Borglum in Washington and saw the letter from the President to Mr. Borglum.

According to Mr. Mix, Mr. Borglum told him that he did not know how to build planes that would surpass those now being constructed, "but that through his friendship with the White House and acquaintance with Mr. Gibson, the engineer in the employ of the British Ministry of Munitions, he would have access to the best foreign designs practices."

Mix Informs Officials

Mr. Mix, according to his statement, became suspicious, and conferred with Mr. Hardesty, a consulting engineer of Washington and a friend of Mr. Mix's father. Mr. Hardesty knew Howad Coffin, the Chairman of the Aircraft Board, and the matter was laid before him, General Squier, Chief Signal Officer of the Army, Colonel Deeds, and Colonel Montgomery of the Military Aircraft Administration. Subsequently it was decided to lay the matter before Vice President Marshall, a friend of Mr. Mix. This was done on Jan. 20, and on the following day the Vice President informed Mr. Mix that he had brought the case to the attention of Secretary Baker.

In his statement Mr. Mix says that after discussion of the matter at the Metropolitan Club in Washington with Mr. Borglum and others he informed Henry Harrison Suplee, consulting engineer of the Dodge Manufacturing Company, that he thought it best to drop all discussion of the proposed company, as Mr. Borglum did not have any designs for a new aeroplane to submit, "but was probably relying upon his official powers to requisition and get certain information from the Government which could be turned over to the new company for construction." Mr. Borglum stipulated, according to Mr. Mix, that he—Mr. Borglum—was not to appear in the new company but that he would be represented in it by Benjamin Harris, President of the Standard Smelting and Refining Company of New York.

Senator Thomas made only the briefest comment in presenting the documents to the Senate. "This shows Mr. Borglum's criticism of the aircraft program to be entirely without merit," he said.

Denial by Borglum

A formal statement given out by Mr. Borglum follows:

"Let us dispose of the two questions separately, raised by Deeds's former agent, Mix, and Mix's engineer. Their first and foremost charge is that I used the President's authority improperly and in a manner unthinkable between men in mutual confidence. I deny this. It is a 'frame-up,' shaped especially to offend, as it properly should, the President. My regret is that it seems to have been successful, and he published, unfairly to me and without warning, some of his letters to me. About this time I received further information from a confidant of the President that the Administration now possessed a club that would put me out of business if I did not quit.

"Their second charge is that I was party to or in some way or another was secretly engaged in aeroplane production, using my position and confidence of the President to this advantage. I deny that falsehood in every detail, as unfounded, without reason or support. I wish also to add, regarding Mix, that he came to my attention through his own charges against the Aircraft Board, and submitted a lengthy typed statement, charging the aircraft department with culpable retardation and delays prejudicial to the interests of the country. The original of this statement was returned to Mr. Mix at his earnest pleadings, after he had confessed that he had been in touch with a uniformed member of the board, and, by his own statement, had been heavily commissioned by that member. Mix is a witness for specific charges of 'crookedness' he himself charges against Colonel Deeds and Deed's 'partners,' and will, if the Government does not persist in whitewashing this entire business, be compelled to appear as a party with Deeds in matters Mix himself designated as 'crooked.'

"Regarding Mr. Baker's statement of pro-German influence: This unfortunate statement from an officer of the Government whose office has resisted successfully every effort to investigate and get at the truth upon any subject relating to the war, and whose department is so amply supplied with advisers, close in the confidence of the Secretary, of Teutonic origin, is ludicrous. I do not here impugn the patriotism of any of these men. I do say, candidly and emphatically, that it is unfair to ask German blood, though born in America, to be as prompt as war demands in the execution of their orders against their Fatherland. Never has a department of a government of a great nation submitted an agent of its executive to such contemptible, unjustified sloughing and general interference as was prosecuted against me in my work, and I challenge Mr. Baker or any department of the Government to investigate or to explain and justify in any way their conduct in this.

"Frame-Up Deliberately Planned"

"Every American knows now that the War Department has systematically directed the opposition to investigate; that every subterfuge has been resorted to to gain time. Every investigation—and there have been many—has been instituted with a prayer and hope that a clean bill would be secured, and it is now clear that this final 'frame-up' was deliberately planned and laid in preparation to destroy the value and validity of my investigation.

"It should not be forgotten that I have been accused indirectly of the death of Blakeley, a fine, sober youth, who lost his life at Mineola on the 17th of January through the failure of the Liberty motor; also, that I have been accused of stealing a trunkful of blueprints of a famous Italian aeroplane, and that these, with the present charges and possibly others, have been in the hands of the Military Intelligence Department, Secretary Baker, Mr. Coffin, and now, I learn, of Vice President of the United States Marshall, together with the President of the United States, and that no use was made of them, and that I have never been given an opportunity to explain or know of them officially until it became apparent last week that I would stand by the subject until it was investigated.

"I am sorry, more than I can say, that we should suddenly be thrown into a difference over a proper affair, an honest investigation that honest men never object to, and I cannot but think that the Secretary of War's blow at me is other than a colossal blunder. Personally, I am not of the remotest importance in this matter. The nation demands to know why a billion dollars in eleven months has provided us with no planes. Next, it demands to know who is responsible. There has a graver question arisen: Who is it that is so powerful, and where are they, that makes it impossible and dangerous to the character and honor of men that they shall ask this question?

"GUTZON BORGLUM."

May 11

The Bristol Scout Discussion

The Senate Military Affairs Committee learned of new disappointments in the aircraft program. After their weekly conference with the War Council, members of the committee said serious difficulties were being encountered in the manufacture of the Bristol fighting plane. The aeroplane has not been accepted and one member of the committee declared his belief that it never would be accepted by the War Department.

The main obstacle to the production of the Bristol machine has been engine trouble. It has been impossible to date to fit it with an engine which would function satisfactorily, according to members of the committee. When the Liberty motor was tried the radiation was inadequate and efforts to change the machine to get around this difficulty have proven unsatisfactory, it was stated.

The Bristol aeroplane was one of the types of fighting machine on which much reliance was placed. The Military Affairs Committee's discovery of the situation added to the impatience in Congress over the delays in the aircraft program and stimulated the determination to go to the bottom of the reasons for the alleged failure of aircraft production.

My Brave Birdman

By EDA ELIZABETH LYONS

Far swifter than the eagle bold
Through misty heights you fly,
Your realm it is in cloudland fair,
Your kingdom, 'tis the sky.

Do you ever lose the stirring thrill
When through vast space you soar,
When you leave the big world far below
With its tumult and its roar?

Do you ever feel as if your soul
Were scaling with you too?
Do you ever think of those on earth
Who watch and pray for you?

Or does the call, so loud and clear
Of duty, fill your ears,
The thought of God and right and truth
Drive far from you all fears?

I know it must; I know it does,
For with brave heart you risk your all,
The unknown holds for you no dread,
Death holds for you no pall.

So go, my lad, my brave birdman,
To combat far above,
And know that come what will or may,
It cannot kill our love.
